MMWR™
MORBIDITY AND MORTALITY WEEKLY REPORT

Heat-Wave–Related Mortality — Milwaukee, Wisconsin, July 1995

During July 12–15, 1995, a heat wave* occurred in major portions of the midwestern and eastern United States. Record-high temperatures were recorded at approximately 70 locations, ranging from the central and northern Great Plains to the Atlantic coast (*1*) and caused substantial numbers of heat-related illnesses and deaths in some locations (*2*). In Milwaukee, Wisconsin (1994 estimated population: 938,112), maximum daily temperatures ranged from 91 F (32.7 C) to 103 F (39.5 C), and average daily humidity was as high as 70%. This report summarizes the investigation by the Milwaukee County Medical Examiner's Office (MCMEO) and the Milwaukee Department of Health and Social Services of heat-related deaths in Milwaukee during the heat wave and presents four case reports.

Investigation of Deaths

During July 13–23, MCMEO received reports of and investigated 197 deaths. Of these, 91 (46%) were determined to be related to the heat wave. Deaths were considered heat-related if 1) the decedent's measured body temperature at the time of death was ≥105 F (≥40.4 C), or 2) there was evidence of high environmental temperature—usually ≥100 F (≥37.7 C)—at the scene of death.

Hyperthermia or excessive heat was cited as the underlying or direct cause for 34 (37%) of these 91 deaths and as an important contributing cause for 57 (63%). The 91 decedents ranged in age from 1 year to 97 years (median: 76 years), and 52 (57%) were male. Psychotropic medications were cited as contributing factors in 15 deaths, and alcohol consumption was cited as a contributing factor in five. Eighty-one (89%) of the deaths occurred during July 14–17, and 34 (42%) of these occurred on July 15 (Figure 1).

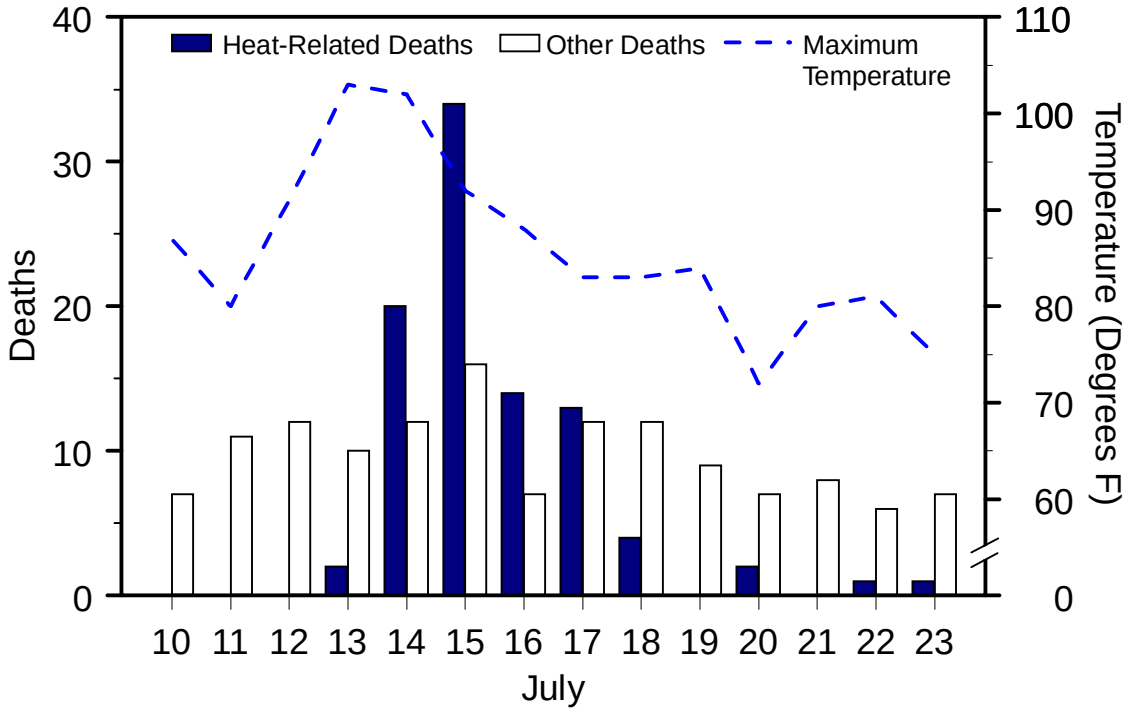
Case Reports

Case 1. On July 13, 1995, a 7-month-old girl was brought to an emergency department because of respiratory arrest but could not be resuscitated. The cause of death was listed by MCMEO as bronchopulmonary dysplasia associated with environmental hyperthermia. She had been receiving home nursing care for congenital respiratory impairment. A window air conditioner was being installed at the time of her death.

*Three or more consecutive days of air temperatures >90 F (>32.2 C).

Heat-Wave–Related Mortality — Continued

FIGURE 1. Deaths reported to the Milwaukee County Medical Examiner's Office and maximum daily temperatures — Milwaukee, Wisconsin, July 10–23, 1995



Case 2. On July 14, 1995, an 82-year-old woman was found dead in her two-story home. A neighbor reported that the decedent had had no health complaints the previous evening. Family members reported that the decedent had used a fan but kept all doors and windows closed because of safety concerns; the wall thermostat registered >90 F (>32.2 C) on the day before death. The immediate cause of death was listed by MCMEO as arteriosclerotic heart disease, with elevated environmental temperature as an important contributing factor.

Case 3. On July 15, 1995, a 24-year-old man with a history of schizophrenia, acute depression, and psychotropic drug use was found dead in the living room of his family residence. The previous day he had reported "not feeling well." The immediate cause of death was listed by MCMEO as environmental hyperthermia, with use of psychotropic medications as an important contributing factor.

Case 4. On July 17, 1995, a 79-year-old woman was found dead in her home. She had last been seen returning from a store on the previous day by a neighbor. The immediate cause of death was listed by MCMEO as arteriosclerotic heart disease, with elevated environmental temperature as an important contributing factor.

Reported by: R Nashold, PhD, P Remington, MD, P Peterson, Center for Health Statistics and Registrar of Vital Statistics, Div of Health, Wisconsin Dept of Health and Social Svcs; J Jentzen, MD, Milwaukee County Medical Examiner's Office, Milwaukee, Wisconsin. R Kapella, National Weather Service, Champaign, Illinois. Health Studies Br and Surveillance and Programs Br, Div of Enivironmental Hazards and Health Effects, National Center for Environmental Health, CDC.

Editorial Note: During periods of sustained environmental heat—particularly during the summer—the numbers of deaths classified as heat-related (e.g., heatstroke) and attributed to other causes (e.g., cardiovascular, cerebrovascular, and respiratory dis-

Heat-Wave–Related Mortality — Continued

ease) increase substantially (*3*). The epidemiology of the heat-related deaths in Milwaukee in 1995 is consistent with previous reports indicating increased risk for heat-related mortality among elderly persons, persons with chronic conditions (including obesity), patients taking medications that predispose them to heatstroke (e.g., neuroleptics or anticholinergics), and persons confined to bed or who otherwise are unable to care for themselves (*4,5*).

Adverse health outcomes associated with high environmental temperatures include heatstroke, heat exhaustion, heat syncope, and heat cramps (*6*). Heatstroke (i.e., core body temperature ≥105 F (≥40.4 C) is the most serious of these conditions and is characterized by rapid progression of lethargy, confusion, and unconsciousness; it is often fatal despite medical care directed at lowering body temperature. Heat exhaustion is a milder syndrome that occurs following sustained exposure to hot temperatures and results from dehydration and electrolyte imbalance; manifestations include dizziness, weakness, or fatigue, and treatment is supportive. Heat syncope and heat cramps usually are related to physical exertion during hot weather; persons with loss of consciousness resulting from heat syncope should be treated by placement in a recumbent position and replacement of electrolytes.

Basic behavioral and environmental measures are essential for preventing heat-related illness and death. Personal prevention strategies should include increases in time spent in air-conditioned environments, intake of nonalcoholic beverages, and incorporation of cool baths into a daily routine. When possible, activity requiring physical exertion should be conducted during cooler parts of the day. Sun exposure should be minimized, and light, loose, cotton clothing should be worn. The risk for heat-induced illness is greatest before persons become acclimatized to warm environments. Athletes and workers in occupations requiring exposure to either indoor or outdoor high temperatures should take special precautions, including allowing 10–14 days to acclimate to an environment of predictably high ambient temperature.

Public health agencies can assist in preventing heat-related illnesses and deaths by disseminating community prevention messages to persons at high risk (e.g., the elderly and persons with preexisting medical conditions) using a variety of communication techniques and establishing emergency plans that include provision of access to artificially cooled environments.

National, State, and Urban Area Vaccination Coverage Levels Among Children Aged 19–35 Months — United States, July 1994–June 1995

The National Immunization Survey (NIS) is an ongoing survey to provide estimates of vaccination coverage levels among children aged 19–35 months in the United States, all 50 states, and selected urban areas. CDC implemented NIS in April 1994 as one element of the five-part Childhood Immunization Initiative (CII), a national strategy to achieve and maintain high vaccination levels among children during the first 2 years of life (*1*). NIS collects quarterly data from all 50 states, the District of Columbia, and 27 urban areas considered to be at high risk for undervaccination (*2,3*). This report provides NIS findings for July 1994–June 1995, which indicate that coverage levels for diphtheria and tetanus toxoids and pertussis vaccine (DTP), *Haemophilus influenzae* type b vaccine (Hib), poliovirus vaccine, and hepatitis B vaccine have met or exceeded the 1995 interim goals of the CII and that coverage for measles-mumps-rubella vaccine (MMR) is within 1 percentage point of the objective.

NIS uses a two-phase sample design: the first phase employs a quarterly random sample of telephone numbers for each survey area and includes administration of a screening questionnaire to respondents aged ≥18 years to locate households with one or more children aged 19–35 months*. Vaccination information is collected for all age-eligible children. All respondents are asked to refer to written records; however, reports from recall also are accepted. During July 1994–June 1995, approximately 1.6 million telephone numbers were called, and 35,440 interviews were completed (an average of 454 interviews per survey area). The overall response rate for eligible households was 71% (range: 57%–86% among the 78 survey sites).

In the second phase, vaccination information is requested from health-care providers for children in surveyed households. During 1994, households were excluded that used records indicating their children received all recommended doses of four specific vaccines.† All households identified in the first and second quarters of 1995 were included in the second phase. Based on exclusions, 30,543 (86%) children were eligible for the second phase; of these, vaccination information was obtained from providers for 13,755 (45%) children. The demographic characteristics and the reported vaccination histories were similar for children with and without provider information. Overall, for 59% of the children in the survey, either written records of having received all of the required doses for the four vaccines were available (29%) or vaccination information based on provider records was available (30%). As previously described, these provider data were used to adjust responses for the entire group of children surveyed (*2–5*). Data from four consecutive quarters yielded 12-month estimates for the United States, the 50 states, the District of Columbia, and the 27 urban areas.

Compared with the previous reporting period (April 1994–March 1995), there were statistically significant increases in national vaccination coverage with three or more doses of poliovirus vaccine (from 84% [95% confidence interval (CI)=±0.9%] to 86% [95% CI=±0.8%]) and with three or more doses of hepatitis b vaccine (from 42% [95%

*For this reporting period, included children born during August 1991–November 1993 (median: age 27 months).

†Four doses of DTP, three doses of poliovirus vaccine, one dose of MMR, and three doses of Hib.

Child Vaccination Levels — Continued

CI=±1.2%] to 51% [95% CI=±1.1%]) (Table 1)[§]. The series-complete coverage estimates for 4:3:1 (i.e., four doses of DTP, three doses of poliovirus vaccine, and one dose of MMR) and 4:3:1:3 (i.e., four doses of DTP, three doses of poliovirus vaccine, one dose of MMR, and three doses of Hib) remained stable.

For every vaccine or series of vaccines, estimated vaccination coverage for the most recent quarter (April–June 1995) was equal to or higher than that for the most recent 12 months. Coverage increased the most for hepatitis B vaccine (62% [95% CI=±1.5%] versus 51% [95% CI=±1.1%]) (Table 1).

During July 1994–June 1995, state-specific estimated coverage levels for the 4:3:1:3 series ranged from 61% to 87% (median: 75%), and for the 4:3:1 series ranged from 64% to 88% (median: 77%) (Table 2). Estimated coverage levels among selected urban areas ranged from 51% to 86% for the 4:3:1:3 series (median: 72%), and for the 4:3:1 series ranged from 55% to 86% (median: 76%) (Table 3). Compared with April 1994–March 1995 (*3*), changes for the 4:3:1:3 series were greatest in Illinois (from 64% [95%

[§]The overlap of three quarters between the current reporting period and the previous reporting period requires a special procedure for calculating the standard error of the difference. Taking the overlap into account leads to a smaller standard error than if the reporting periods were regarded as independent.

*Four doses of diphtheria and tetanus toxoids and pertussis vaccine/diphtheria and tetanus toxoids (DTP/DT), three doses of poliovirus vaccine, and one dose of measles-mumps-rubella vaccine (MMR).

†Four doses of DTP/DT, three doses of poliovirus vaccine, one dose of MMR, and three doses of *Haemophilus influenzae* type b vaccine (Hib).

§Confidence interval.

¶Met the 1995 Childhood Immunization Initiative (CII) goals for three or more doses of DTP, three or more doses of poliovirus, one or more dose of MMR, three or more doses of Hib, and three or more doses of hepatitis B vaccine.

**Met the 1995 CII goals for three or more doses of DTP, three or more doses of poliovirus, one or more dose of MMR, three or more doses of Hib, but not for three or more doses of hepatitis B vaccine.

††Did not meet the 1995 CII goals for at least one of three or more doses of DTP, three or more doses of poliovirus, one or more dose of MMR, or three or more doses of Hib, but did meet the 1995 goal for three or more doses of hepatitis B vaccine.

§§Did not meet the 1995 CII goals for at least one of three or more doses of DTP, three or more doses of poliovirus, one or more dose of MMR, or three or more doses of Hib, or the 1995 goal for three or more doses of hepatitis B vaccine.

Child Vaccination Levels — Continued

CI=±5.2%] to 72% [95% CI=±4.5%]); coverage in Chicago increased from 55% (95% CI=±8.7%) to 65% (95% CI=±7.4%) (*3*).

The 1995 CII interim goal for coverage with three or more doses of DTP was achieved by all states, the District of Columbia, and by all except one of the 27 urban areas; the goal for coverage with three or more doses of Hib vaccine was achieved by 49 states and 24 urban areas. For coverage with three or more doses of poliovirus vaccine, the 1995 interim goal was achieved by 31 states and 16 urban areas; for coverage with one or more dose of MMR vaccine, by 25 states and 16 urban areas; and for coverage with three or more doses of hepatitis B vaccine, by 20 states and 16 urban areas.

Reported by: National Center for Health Statistics; Assessment Br, Data Management Div, National Immunization Program, CDC.

Editorial Note: The findings from the NIS indicate that the 1995 CII interim coverage goals have been met or exceeded for DTP, Hib, poliovirus vaccine, and hepatitis B vaccine (*1*); the coverage estimate for MMR is within 1 percentage point of the goal. This report presents for the first time national quarterly estimates. However, because these estimates reflect changes in coverage in a more timely manner than 12-month estimates, increased variability must be considered when interpreting these quarterly data.

Compared with the previous 12-month estimates, increases in vaccination coverage were greatest for hepatitis B vaccine, probably reflecting substantial progress in the implementation of the infant hepatitis B Advisory Committee on Immunization Practices (ACIP) recommendations (*6*). In addition, coverage for three doses of poliovirus vaccine exceeded the 1995 goal for the first time, and the results for the second quarter of 1995 suggest a continuation of this upward trend. This increase preceded recommendations by the ACIP to encourage administration of the third dose of oral polio vaccine at age 6 months rather than in the second year of life (*7*). National vaccination coverage for 4:3:1 series completion did not change for the 12-month period. Thus, approximately 1 million children still need one or more of the recommended doses of vaccine.

NIS enables identification of differences in coverage levels among states and urban areas and development of area-specific interventions (*3*). States and urban areas that did not meet the 1995 interim goals will need to intensify efforts to meet the 1995 and 1996 goals. Strategies for improving coverage include avoiding missed opportunities for vaccinations by increasing health care providers' awareness of the need to check the vaccination status of children evaluated for other reasons (*8,9*) and linking vaccination to the Special Supplemental Nutrition Program for Women, Infants, and Children (WIC) (*10*). CDC and other public health agencies will continue to use NIS to monitor and target efforts to improve vaccination coverage levels.

Epidemic Malaria — Tadjikistan, 1995

In June 1995, the Tadjikistan Ministry of Health (MOH) and CDC, with support of the U.S. Agency for International Development, began collaborative efforts to strengthen the health information and disease surveillance systems in Tadjikistan (1995 population: 5.7 million) (Figure 1). As part of an initial evaluation in Tadjikistan, the Republican Sanitary and Epidemiologic Service (RSES) and the Parasitology Laboratory of the Institute for Preventive Medicine in the MOH reported a substantial increase in the incidence of malaria since 1991. This report summarizes malaria surveillance data for 1995 in Tadjikistan and describes barriers to implementing effective measures for controlling and preventing malaria in Tadjikistan.

The MOH requires reporting of all malaria cases; reporting sources include physicians and feldshers (health-care workers similar to physician's assistants who often are the first contact patients may have with the medical system, especially in rural

FIGURE 1. Location of Tadjikistan

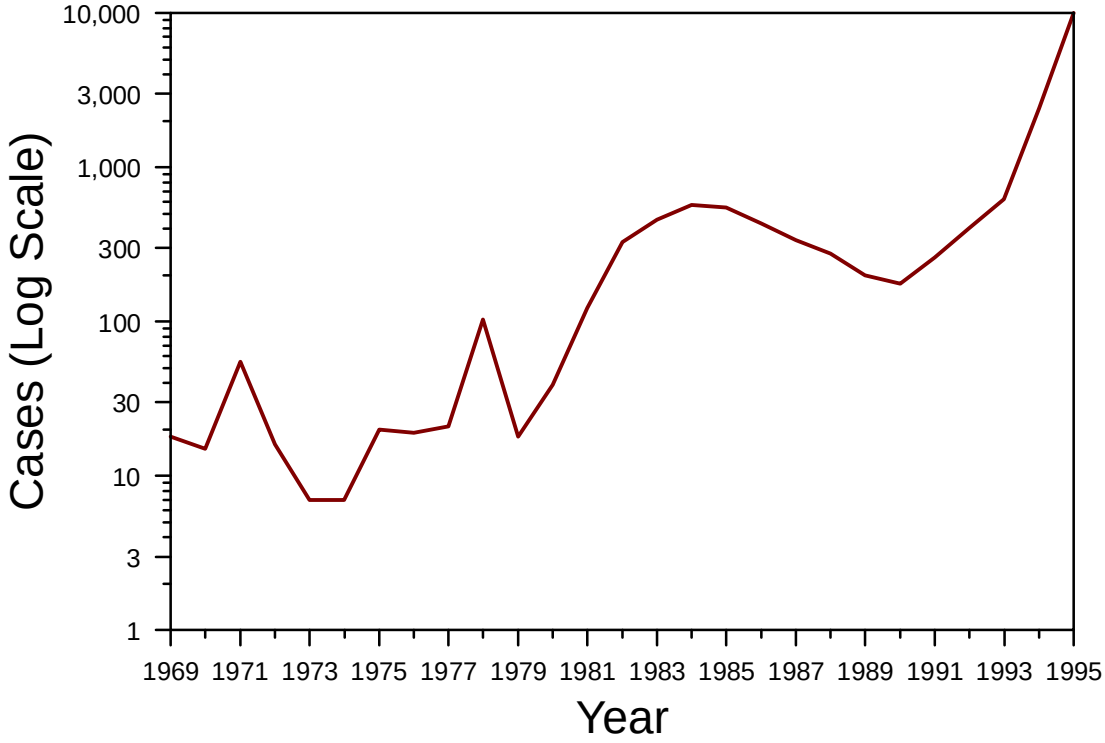
Epidemic Malaria — Continued

areas) who examine patients in hospitals, polyclinics, diagnostic centers, ambulatory clinics, or individual feldsher stations. All cases of malaria—whether confirmed or suspected—must be reported to the MOH within 12 hours. Each case is reviewed, and an investigation may be initiated to examine the diagnosis, exposure, and treatment. Cases enumerated in the surveillance system are those with a final diagnosis of malaria, based on the clinician's evaluation and/or results of the investigation, and may not require laboratory confirmation.

Historically, reported malaria data in Tadjikistan were assessed for validity through a systematic random-sample surveillance system requiring that a blood slide of every 10th smear-confirmed case be sent to the RSES for confirmation; the RSES then sent the slides to the Institute of Preventive Medicine for additional confirmation. The system also required that a blood slide of every 10th smear performed for initially suspected cases that were investigated but not confirmed be sent to the Sanitary and Epidemiologic Service at the oblast (state) level for examination. During the fourth quarter of 1995, this system was unreliable because of shortages of trained personnel.

During the 1960s and 1970s, sporadic cases of infection with *Plasmodium vivax* occurred in persons in Tadjikistan who resided in the area of the Amu Darya River basin that separates Tadjikistan from Afghanistan; from 1972 through 1978, annual case counts were consistently ≤21 (Figure 2). Malaria transmission in Tadjikistan was limited by mosquito-eradication efforts that included aerial spraying with insecticides. Following the start of the war in Afghanistan in 1979, the number of reported cases in Tadjikistan increased sharply, peaking at 571 cases (12.7 per 100,000 population) in 1984, reflecting in part disruption of intensive efforts for mosquito control in both Tad-

FIGURE 2. Reported cases of malaria* — Tadjikistan, 1969–1995



*Cases reported to the Tadjikistan Ministry of Health by physicians and feldshers.

Epidemic Malaria — Continued

jikistan and Afghanistan. Mosquito-control activities were resumed in the mid-1980s, and the total number of reported malaria cases in Tadjikistan had declined to 176 in 1990.

Mosquito-control operations were curtailed in 1991 because of financial constraints and discontinued in 1992. Beginning in 1991, the annual number of confirmed cases of malaria increased dramatically (Figure 2). The 619 cases of malaria reported in 1993 included the first reported cases of *P. malariae* and *P. falciparum*. In 1994, of the 2411 total cases of malaria, 54 (2.2%) were identified as *P. falciparum*; the remainder were identified as *P. vivax* or *P. malariae* infection. The overall incidence of malaria in 1994 was 43.4 per 100,000 population. Of the 2411 total cases, 1638 (70.7%) were reported from Hatlon Oblast (86.7 per 100,000), and 446 (18.5%) were reported from the Gorno-Badakhshan Autonomous Region (227.3 per 100,000). Of the cases reported from Hatlon Oblast, the incidence was highest in those districts bordering Afghanistan. In addition, in at least three administrative districts with populations of approximately 30,000 each, the incidence was ≥300 per 100,000.

During January–September 1995, a total of 4332 cases of malaria were reported, a 146% increase over the same period in 1994 (1764 cases). Although the final total number of new malaria cases in Tadjikistan in 1995 is unknown, an estimated 10,000 cases occurred, based on historical ratios of initial reports to confirmed cases; however, few of these new cases were slide-confirmed. In addition, during January–September 1995, 470 cases were reported in the capital city of Dushanbe (88.2 per 100,000). Although most of these cases occurred among persons who probably acquired infection in the southern oblasts bordering Afghanistan, approximately 24% did not have confirmed recent travel histories to a malaria-endemic area and may have acquired infection locally or these cases may represent relapses. More detailed epidemiologic description of cases (e.g., age and sex) and an accurate number of malaria-related deaths are not available. Chloroquine resistance has not been reported, although detailed drug-sensitivity studies have not been conducted.

Reported by: B Shoismatullaev, Republican Sanitary and Epidemiologic Service; A Sharipov, Kurgan-Tyube Zone Sanitary and Epidemiologic Svc; A Umarova, N Elizarova, F Odinaev, Institute of Preventive Medicine; and I Usmanov, Central Offices, Tadjikistan Ministry of Health. International Health Program Office; Malaria Section, Epidemiology Br, Div of Parasitic Diseases, National Center for Infectious Diseases, CDC.

Editorial Note: An estimated 40% of the world's population is at risk for malaria infection; each year, 300–500 million clinical cases and 1.5–2.7 million malaria-associated deaths occur (*1*). Important components of the Global Malaria Control Strategy described by the World Health Organization (WHO) are recognition of areas at risk for outbreaks of malaria and epidemic preparedness (*2*).

Factors associated with the increased risk for epidemic malaria in Tadjikistan include the large population movements near the Afghanistan border, adverse economic conditions, breakdown of health-care services, shortages of trained public health personnel, and ongoing civil war that has constrained epidemiologic investigation and implementation of control activities (*3*). Systematic preventive measures—including mosquito control—have been suspended because of shortages of gasoline, equipment, and insecticides. Production of crops that require irrigation in an arid area (e.g., rice and corn) also is increasing, resulting in an increase in suitable anopheline breeding sites and possibly contributing to the increase in malaria transmission. Since the government of Tadjikistan declared independence in September 1991, political un-

Epidemic Malaria — Continued

rest and a decline in economic conditions have resulted in an exodus of trained epidemiologists and support personnel to other countries. Of 200 trained epidemiologists in the Tadjikistan RSES before independence, <25 remain. Underreporting also is increasing as persons are less likely to seek health-care services. In addition, although WHO has provided large quantities of antimalarials, only 50%–70% of cases have received optimal treatment with chloroquine and primaquine to treat the blood-stage parasites and to prevent relapses of *P. vivax* infection.

Infection with *P. falciparum* in a population with no prior exposure could cause severe illness with high case-fatality rates among both children and adults. Because many cases in Tadjikistan were imported among refugees returning from northern Afghanistan, an area with chloroquine-resistant *P. falciparum*, surveillance for drug resistance especially is important for development of treatment protocols.

Malaria transmission in Tadjikistan occurs primarily from the end of May through November. Because of the potential for intensification of the malaria epidemic, the surveillance system needs to be strengthened and include collection of travel and exposure history to help target control measures. Optimal case management will require rebuilding diagnostic capability, ensuring ample supplies of antimalarial drugs, and having standardized treatment protocols. Improving the ability to monitor anopheline populations will focus control measures and target the use of insecticides and aerial and house spraying. A needs assessment will be necessary to assist in developing enhanced surveillance, improved case management, and vector control, and to guide assistance from the international donor community.

U: Unavailable -: no reported cases

*Mortality data in this table are voluntarily reported from 121 cities in the United States, most of which have populations of 100,000 or more. A death is reported by the place of its occurrence and by the week that the death certificate was filed. Fetal deaths are not included.

†Pneumonia and influenza.

§Because of changes in reporting methods in these 3 Pennsylvania cities, these numbers are partial counts for the current week. Complete counts will be available in 4 to 6 weeks.

¶Total includes unknown ages.

The *Morbidity and Mortality Weekly Report (MMWR)* Series is prepared by the Centers for Disease Control and Prevention (CDC) and is available free of charge in electronic format and on a paid subscription basis for paper copy. To receive an electronic copy on Friday of each week, send an e-mail message to *lists@list.cdc.gov*. The body content should read *subscribe mmwr-toc*. Electronic copy also is available from CDC's World-Wide Web server at *http://www.cdc.gov/* or from CDC's file transfer protocol server at *ftp.cdc.gov*. To subscribe for paper copy, contact Superintendent of Documents, U.S. Government Printing Office, Washington, DC 20402; telephone (202) 512-1800.

Data in the weekly *MMWR* are provisional, based on weekly reports to CDC by state health departments. The reporting week concludes at close of business on Friday; compiled data on a national basis are officially released to the public on the following Friday. Address inquiries about the *MMWR* Series, including material to be considered for publication, to: Editor, *MMWR* Series, Mailstop C-08, CDC, 1600 Clifton Rd., N.E., Atlanta, GA 30333; telephone (404) 332-4555.

All material in the *MMWR* Series is in the public domain and may be used and reprinted without permission; citation as to source, however, is appreciated.
