Cluster of HIV-Infected Adolescents and Young Adults — Mississippi, 1999

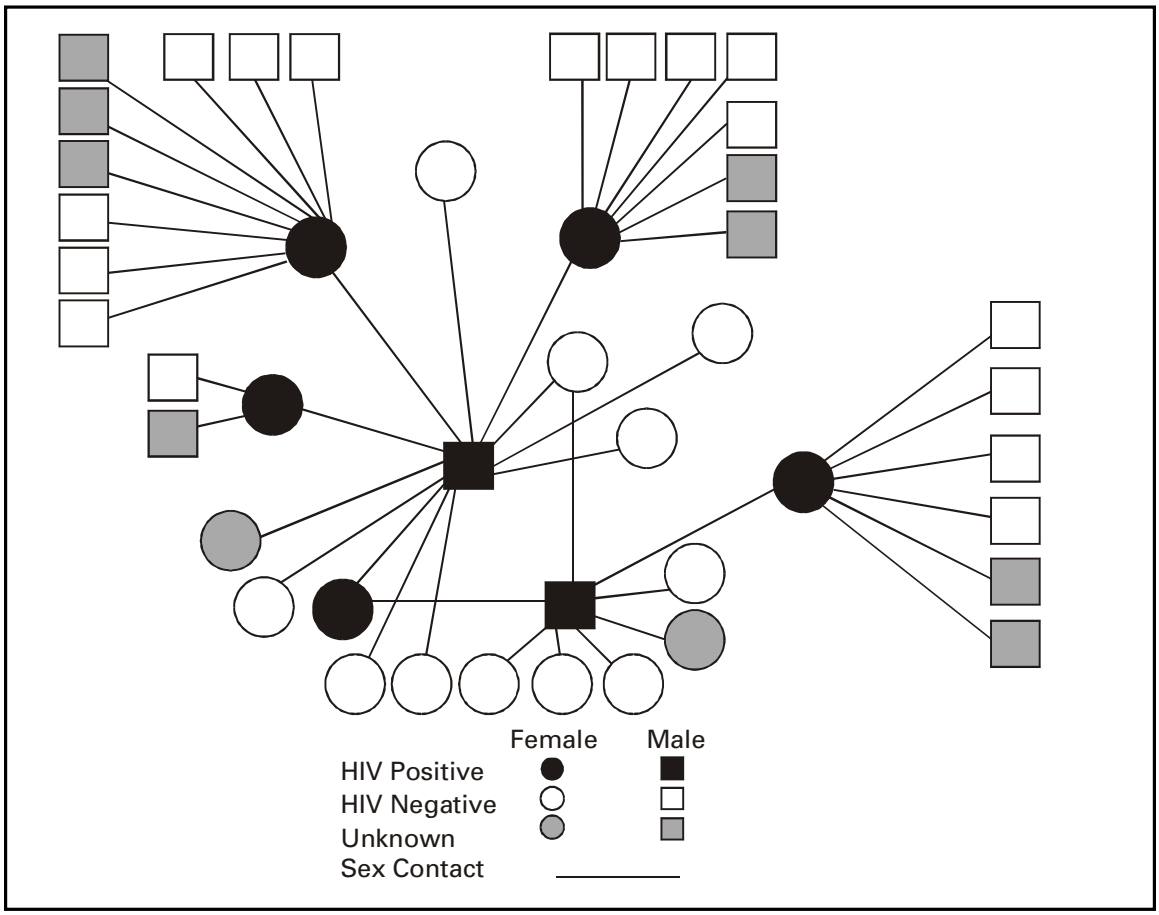
From February through June 1999, seven human immunodeficiency virus (HIV)-infected young persons were identified in a small town in rural Mississippi. Two persons were identified through routine voluntary HIV testing during sexually transmitted disease (STD) evaluations, and five were identified subsequently through contact investigation by the local health department. Contact investigation identified sex partners and social contacts (i.e., persons who shared social surroundings) and defined a social network of 122 sex and social contacts. Seven (9%) of 78 persons tested from the social network were HIV-infected. Within the social network, a sexual contact network of 44 persons (the seven HIV-infected persons and their sex partners) was identified. The Mississippi State Department of Health asked CDC to join the investigation to describe further the cluster and help direct prevention efforts. This report summarizes the investigation of this cluster and underscores the need for HIV prevention and treatment in rural areas.

HIV-infected persons and uninfected sex partners were interviewed, and a case-control analysis was performed to assess risk factors for infection. Uninfected female social contacts who had not had sex with the infected men also were interviewed and compared with the HIV-infected women to assess risk factors for exposure. Kruskal-Wallis (KW) and Fischer exact (FE) statistical tests were used. For HIV-infected persons, sensitive-less sensitive detuned assays (*1*) were performed to identify persons probably infected within 180 days of diagnosis, and CD4+ cell counts and plasma HIV-1 RNA levels were measured to identify need for treatment. Questionnaires were mailed to local internists and family practitioners to establish HIV care patterns and practices in the area.

Persons in the sex network (Figure 1) had a median age of 21 years (range: 13–45 years), and all were black. The network was located in an economically depressed neighborhood with few organized social activities. Interviews with the seven HIV-infected persons (five women) and 22 uninfected sex partners (10 women) indicated that HIV was acquired locally through heterosexual contact. Of the 29 persons, 15 (52%, [four infected and 11 uninfected]) had a history of other STDs, and 28 (97%) reported multiple lifetime sex partners. Three of five infected women had STD co-infection when HIV was diagnosed. Factors associated with HIV infection in the five women were young age (median: 16 years, compared with 25 years for the infected men [KW p=0.05] and 20.5 years for the uninfected women [KW p=0.04]); a stated preference for "much older" sex partners (three of five infected women compared with one of 10 uninfected women

Sex Network — Continued

FIGURE 1. Sex network of seven persons with HIV infection — Mississippi, 1999



[FE p=0.08]); and having had a sex partner who was at least 10 years older (three of four responding infected women compared with two of 10 uninfected women [FE p=0.09]). Infected persons also began engaging in sex at a younger age (median: 13 years; range: 11–14 years compared with uninfected persons, median: 14.5 years, range: 12–17 years; [KW p=0.08]). Alcohol use, drug use, and exchange of sex for alcohol, drugs, or money were not associated with HIV infection in this cluster.

Interviews with seven uninfected female social contacts indicated they were similar to the infected women in age (median: 18 years for the social contacts). Common characteristics of infected women and social contacts included low socioeconomic status (seven of 12 women received federal aid), absentee fathers (nine of 12 persons), truancy (six of nine persons in school), and school failure (six of 12 persons having repeated at least 1 year in school). No social contacts reported having had sex partners that were ≥10 years older than themselves compared with three of the four infected women who responded.

Laboratory results and medical histories indicated that antiretroviral therapy was recommended in all infected persons (*2*). Two persons had seen a doctor since HIV infection was diagnosed. Five of seven persons did not know treatment for HIV infection existed. Of five persons who remembered being referred to care on diagnosis, all were referred to a facility >2 hours away, and one had been seen at that facility. The six remaining persons were willing to be linked to care once they knew HIV care was available locally.

Sex Network — Continued

Survey responses were received from five of six internists and two of six family practitioners. Of the seven responding physicians, one cared for approximately 60 HIV-infected persons and was the only one who reported practices consistent with guidelines for monitoring and treating asymptomatic persons. The others had provided ongoing care to <10 HIV-infected persons; most reported referring persons for care because they lacked experience in HIV treatment.

Reported by: State health officers, state epidemiologist, district health officers, and disease intervention specialists, Mississippi State Dept of Health. Div of Applied Public Health Training, Epidemiology Program Office; Div of HIV/AIDS Prevention–Intervention Research and Support, and Div of HIV/AIDS–Surveillance and Epidemiology, National Center for HIV, STD, and TB Prevention; and EIS officers, CDC.

Editorial Note: The findings in this report suggest that STDs and multiple sex partners in small town sex networks provide a setting for the transmission of HIV among adolescents in the rural South. HIV infection can spread rapidly through sex networks in low-prevalence rural areas (*3*). Among adolescents, disadvantaged black women in the South have some of the highest HIV infection rates in the United States and must be a high priority for prevention activities (*4*).

The method by which persons in this cluster were identified underscores the importance of providing routine voluntary HIV counseling and testing services during STD evaluations. In addition, partner counseling and referral services can be especially useful for identifying partners in need of prevention services and for identifying the extent of the HIV-infection network. This cluster also highlights the challenges of service delivery in a rural area with limited HIV prevention and treatment resources.

The age-discrepant relations in this cluster have implications for both HIV transmission and primary prevention programs. Adult partners contribute substantially to STDs and pregnancies among teenagers (*5*). Young women are at risk for HIV infection at an earlier age than are heterosexual men, probably because the women are infected by older sex partners (*6*). Age difference also may affect adolescents' abilities to negotiate safer sex and condom use. Prevention efforts should address age-discrepant relationships.

Secondary prevention measures, such as links to ongoing HIV care and antiretroviral therapy, can improve health and survival and potentially decrease, although not eliminate, infectivity. Following this investigation, efforts to link HIV-infected persons to care have been extended in this health district. Challenges to secondary prevention in rural areas include awareness of treatment options and identification and training of appropriate local HIV care providers.

In this cluster, identification of a qualified local care provider facilitated linkage to care and provided a potential point of coordination for social work, mental health care, and case-management services by the local health department. Where no experienced HIV care provider exists, identifying a practitioner willing to accept this role and to develop an ongoing relationship with a remote consultant would be an alternative.

Nutritional Assessment of Adolescent Refugees — Nepal, 1999

During 1990–1993, 83,000 ethnic Nepalese fled from Bhutan to refugee camps in southeast Nepal after new citizenship policies were enacted by the Bhutanese government. Although annual nutrition surveys of children aged <5 years had been conducted by international agencies, no anthropometric assessment of adolescents had been performed since the refugees arrived in 1990. After withdrawal of a fortified cereal from their rations, the number of reported cases of angular stomatitis (AS) (i.e., thinning and/or fissuring at the angles of the mouth, a sign of possible vitamin deficiency) increased six-fold during December 1998–March 1999 (from 5.5 to 35.6 cases per 1000 refugees) (Santa Tamang, MD, Save the Children Fund, United Kingdom, personal communication, 1999). The highest rates of AS were found among children and adolescents. In October 1999, CDC was invited by the World Food Programme and the United Nations High Commissioner for Refugees to assess the health status of adolescent refugees. This report summarizes the investigation, which indicated a high prevalence of low body mass index (BMI), anemia, low vitamin A status, and signs of micronutrient deficiencies among adolescent refugees.

The nutritional status of a sample of refugees aged 10–19 years was assessed using anthropometry, hemoglobin measurement, laboratory testing, and a limited physical examination. Height was measured to 0.04 inches (1 mm) using 6.9 foot (2 m) height boards, and weight was measured to the nearest 3.5 ounces (100 g) using digital bathroom scales. BMI was defined as weight (in kilograms)/(height^2 [in meters]). Low BMI was determined by comparing a person's BMI to that of persons of similar age and same sex in the World Health Organization (WHO) adolescent reference population (*1*). A fingerstick blood sample was collected to determine hemoglobin concentration using a hemoglobinometer. Anemia was defined according to WHO criteria (*2*). From half the participants, serum was collected by venipuncture for retinol (vitamin A) testing by high performance liquid chromatography (*3,4*). A retinol level <20 µg/dL was considered low (*3*).

Participants aged 10–19 years were chosen by systematic random sampling from camp registration data of 26,235 adolescents; 400 were needed to generate prevalence estimates for low BMI and anemia. An additional 20% were chosen to ensure an adequate sample after accounting for persons who could not be located or who refused to participate. Data were analyzed using EpiInfo version 6.04b. Chi-square or Fisher's exact tests were used to compare data. For point estimates of prevalence rates, 95% confidence intervals (CIs) were calculated by the quadratic method.

Of the 495 selected adolescents, 463 (94%) were enrolled; 236 (51%) were female, 253 (55%) were aged 15–19 years, and 167 (36%) (95% CI=32%–41%) had low BMI. Boys were twice as likely as girls to have low BMI (48% versus 24%; p<0.01), and participants

Nutrition Assessment — Continued

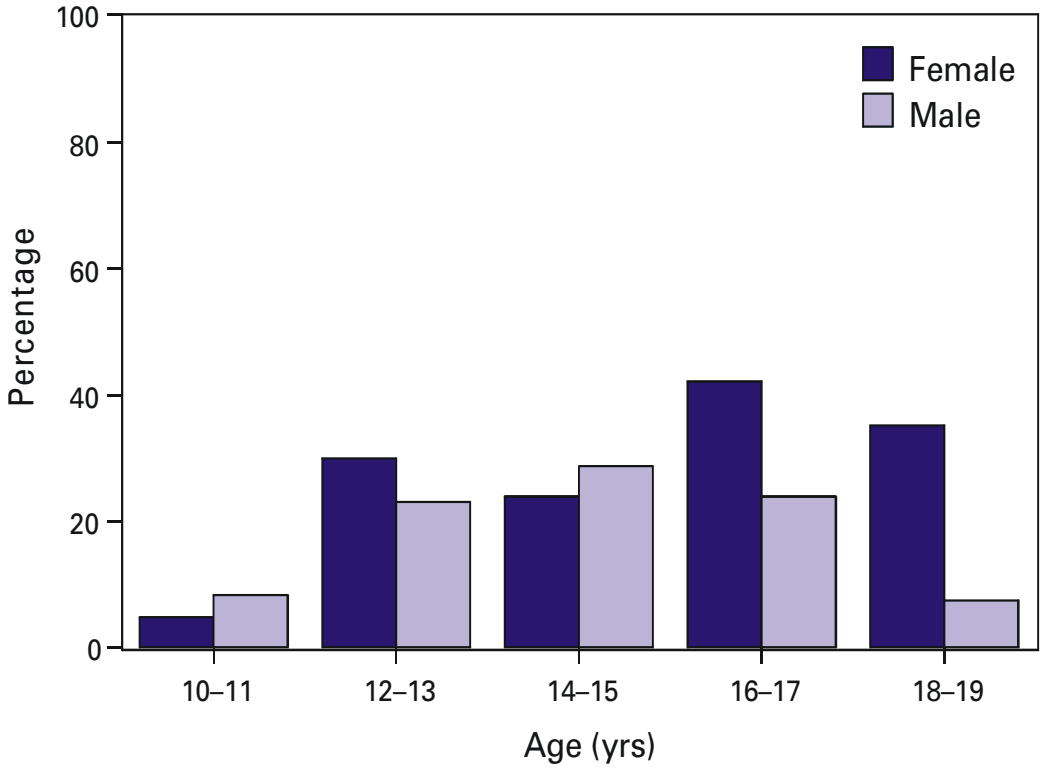
aged 10–14 years were 1.7 times as likely to have low BMI as those aged 15–19 years (64% versus 37%; p<0.001). The prevalence of low BMI declined with age among both sexes; however, this decline was substantially more rapid among girls.

Among the 458 participants who reported no recent iron tablet supplementation, 111 (24%) (95% CI=20%–28%) were anemic. The mean and median hemoglobin values were both 13.0 g/dL (standard deviation [SD]=1.7). The prevalence of anemia among girls who received no iron supplementation increased sharply after age 11 years; 33% of girls aged ≥12 had anemia, peaking at age 16–17 years (Figure 1) (trend test, p=0.05); 49 (37%) of 134 girls who reported having experienced menarche had anemia compared with 17 (17%) of 99 who had not (p=0.001). The prevalence of anemia among boys peaked at age 14–15 years and then decreased with age (Figure 1).

Among the 190 participants assessed, 49 (26%) (95% CI=23%–30%) had retinol levels that suggested low vitamin A status. The mean retinol level was 24 µg/dL (SD=6.8) and the median was 23 µg/dL. Two participants (1%) had serum retinol values <10 µg/dL. Low serum retinol status was unrelated to age or sex.

On physical examination, participants showed signs of possible micronutrient deficiencies; 133 (29%) of 463 participants had AS. One participant had spontaneous gum bleeding and 27 (6%) had gums that bled upon touch. Tingling or burning in the hands or feet during the 30 days preceding the investigation was reported by 41% of the participants. Although severe goiter from iodine deficiency was not found on physical examination, three participants had a grade I goiter and one had a grade II goiter (*5*).

FIGURE 1. Prevalence of anemia among adolescent refugees, by age and sex — Nepal, 1999



Nutrition Assessment — Continued

Reported by: World Food Programme, United Nations High Commissioner for Refugees, Save the Children Fund, United Kingdom. Div of Nutrition and Physical Activity, National Center for Chronic Disease Prevention and Health Promotion; Div of Emergency Environmental Health Svcs, and Div of Laboratory Sciences, National Center for Environmental Health; and an EIS Officer, CDC.

Editorial Note: In 1992, a surveillance system was established in refugee camps in Nepal (*6*). This system allowed health-care providers to identify and report the increase in AS cases that led to this investigation.

Although low BMI was common among refugee adolescents, the prevalence of low BMI did not exceed that of adolescents from the general population of Nepal (*7*). Iron deficiency may affect up to two-thirds of pregnant women in developing countries and those who enter pregnancy with adequate iron stores are more likely to complete pregnancy without developing iron deficiency (*8*). The findings in this report indicate that adolescent female refugees in Nepal are at risk for iron deficiency.

The prevalence of low vitamin A status among participating adolescents was high. Persons aged 12–17 years may exhibit night vision problems when serum retinol levels are <20 µg/dL (*9*). Few participants had detectable goiter probably because iodine deficiency was avoided as a result of the distribution of iodized salt.

The findings in this report are subject to at least three limitations. First, because the WHO reference population for evaluating BMI is based on data from the National Health and Nutrition Examination Survey of U.S. adolescents, the prevalence of low BMI among adolescent refugees in Nepal may be overestimated (*10*). Second, clinical evaluation for some micronutrient deficiencies has not been standardized. Third, the sensitivity and specificity of signs or symptoms of specific micronutrient deficiencies among adolescents has not been established.

On the basis of findings from this investigation, recommended nutritional improvements for adolescents in Nepal included distributing iron and folate supplements to girls, ensuring adequate vegetable oil fortification with vitamin A, continuing surveillance for signs of micronutrient deficiencies, and adding a fortified source of micronutrients to the food ration to increase daily nutrient consumption to international standards. Long-term recommendations included the support and expansion of vegetable production in camp gardens and the raising of poultry. Since this investigation, continued surveillance for signs of micronutrient deficiencies and expansion of vegetable production in camp gardens has occurred; the addition of whole lentils to the ration is planned.

Progress Toward Poliomyelitis Eradication — Ethiopia, 1997–August 2000

In 1988, the World Health Assembly resolved to eradicate poliomyelitis globally by 2000 (*1*). Following the signing of the Yaounde Declaration on Polio Eradication in Africa in 1996, Ethiopia joined global efforts toward polio eradication (*2*). Since then, Ethiopia has accelerated implementation of polio eradication strategies. This report summarizes progress toward polio eradication in Ethiopia during 1997–August 2000 and highlights the remaining challenges toward achieving the goal.

Routine Vaccination Coverage

During 1990–1999, reported coverage of children aged 0–11 months with 3 doses of oral poliovirus vaccine (OPV3) ranged from 20%–90%. The last comprehensive coverage survey conducted in 1995 estimated OPV3 coverage at 36%. Preliminary data from the 2000 Ethiopia Demographic and Health Survey estimates average OPV3 coverage at 35%.

Supplemental Vaccination Activities

In 1996, Ethiopia conducted Subnational Immunization Days* (SNIDS) for the first time, targeting 2.5 million children aged <5 years in nine major cities. Since then, the country has conducted two rounds of National Immunization Days† (NIDs) annually. Implementation of NIDs during 1997–1999 and SNIDs in 2000 has reached >90% of the target population (Table 1), including areas with limited access to routine health services. In 1999, intensified campaigns with delivery of vaccine house-to-house were conducted in three regions (Afar, Benshangul, and Somali) that had performed poorly in previous

*Focal mass campaigns in high-risk areas over a short period (days to weeks) in which two doses of OPV are administered to all children, usually aged <5 years, regardless of vaccination history, with an interval of 4–6 weeks between doses.

† Mass campaigns over a short period (days to weeks) in which two doses of OPV are administered to all children, usually aged <5 years, regardless of vaccination history, with an interval of 4–6 weeks between doses.

Poliomyelitis Eradication — Continued

years. As a result, 541,996 more children were reached in these regions compared with 1998 NIDs, which used only fixed-site vaccinations.

Despite improvements in vaccine delivery, pockets of unvaccinated children remain. During the 2000 house-to-house SNIDs, efforts were made to detect the proportion of children never vaccinated by routine services or during NIDs. Of children vaccinated during the 2000 SNIDs, an average of 25% (range: 1%–100%) had never received vaccine.

Acute Flaccid Paralysis Surveillance

Surveillance for acute flaccid paralysis (AFP) was initiated in 1997. During 1997–August 2000, the nonpolio AFP rate increased from 0.10 to 0.44 per 100,000 children aged <15 years (a sensitive system is defined as ≥1 per 100,000 children aged <15 years) (Table 2).

Surveillance performance among the 11 regions of Ethiopia varies substantially. Wild poliovirus isolates have been isolated in zones (subregional administrative units) where AFP surveillance is improving and reached nonpolio AFP levels >0.5. However, only 26 of Ethiopia's 71 zones have achieved this level; the more densely populated zones in central Ethiopia have nonpolio AFP rates <0.5, and 25 zones have not reported any AFP cases during 2000. These 25 zones also have very low (<20%) routine OPV3 coverage.

The proportion of adequate stool specimens from AFP case-patients (i.e., two stool specimens collected at an interval of at least 24 hours within 14 days of onset of paralysis and adequately shipped to the laboratory) has improved from 12% in 1998 to 44% in 2000 (Figure 1). All stool specimens routinely are split and tested in both the Ethiopia Health and Nutrition Research Institute (EHNRI) polio laboratory and the World Health Organization (WHO) accredited national laboratory in Uganda. The EHNRI polio laboratory is expected to attain WHO accreditation status by the end of 2000.

TABLE 1. Number of children reached by National Immunization Days (NIDs)* and Subnational Immunization Days (SNIDs)†, by year — Ethiopia, 1997–August 2000

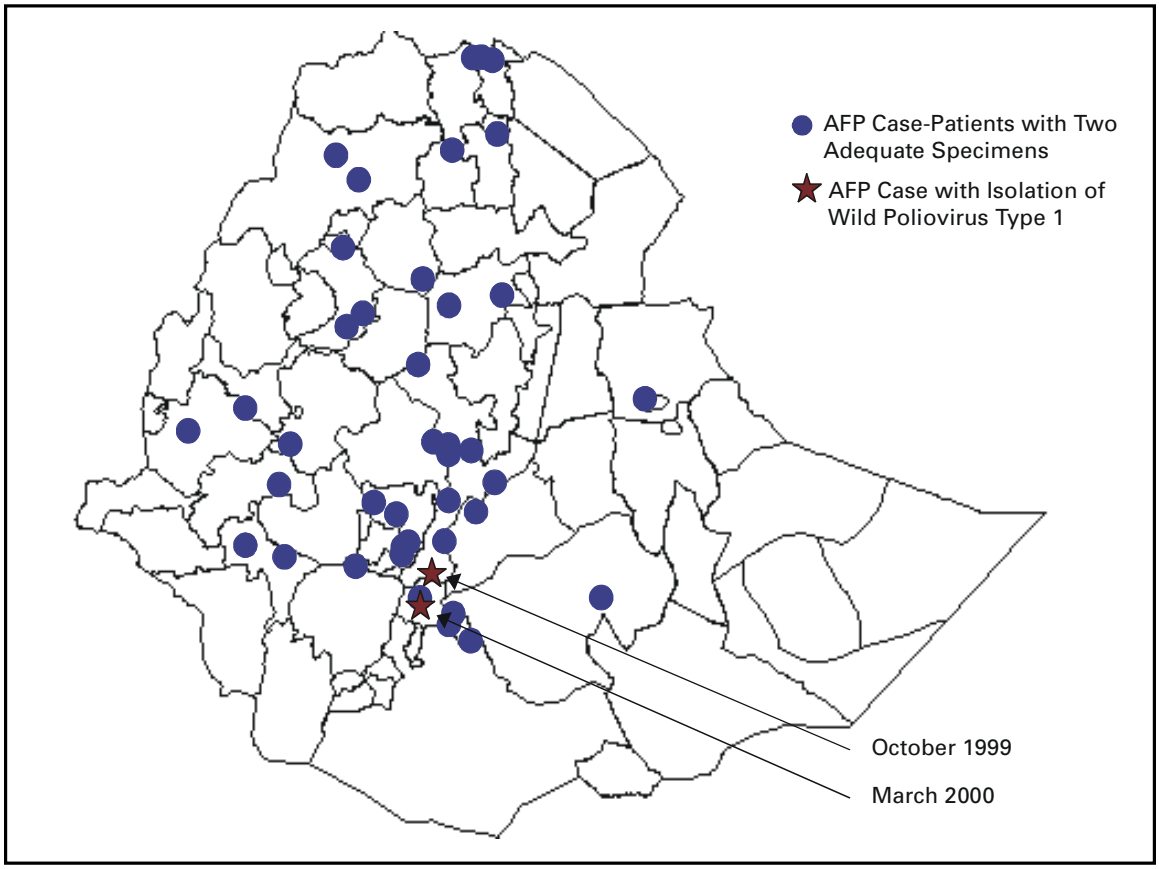
Poliomyelitis Eradication — Continued

FIGURE 1. Distribution of wild poliovirus isolates and acute flaccid paralysis (AFP) case-patients with adequate stool specimens — Ethiopia, January–August 2000*



* One person with a wild poliovirus isolate had onset of symptoms in October 1999.

Incidence of Polio

Until March 2000, AFP surveillance had not detected wild poliovirus in Ethiopia. In March 2000, the Johannesburg polio reference laboratory confirmed isolation of the first wild poliovirus type 1 (P1) in an AFP case from Oromia region with onset of paralysis in October 1999. A second isolate was reported in August 2000, with paralysis onset in March 2000. Neither of these virologically confirmed polio case-patients had received any doses of OPV. Genetic sequencing of polioviruses isolated from these cases revealed that they were indigenous to Ethiopia and unlike those polioviruses isolated in bordering countries.

Reported by: Ministry of Health, Addis Ababa, Ethiopia. Vaccine Preventable Diseases Unit, Regional Office for Africa, World Health Organization, Hrare, Zimbabwe. Dept of Vaccines and Biologicals, World Health Organization, Geneva, Switzerland. Respiratory and Enteric Viruses Br, Div of Viral and Rickettsial Diseases, National Center for Infectious Diseases; Vaccine Preventable Disease Eradication Div, National Immunization Program, CDC.

Editorial Note: Rapid progress has been achieved in implementing polio eradication strategies in Ethiopia, one of the major polio reservoirs in the Africa Region (*3*). Recent improvements in AFP surveillance led to the detection of indigenous wild poliovirus transmission. In addition, the number of children reached by NIDs and SNIDs has increased annually. The house-to-house approach in parts of the country during 1999

Poliomyelitis Eradication — Continued

and 2000 resulted in increased coverage of children aged <5 years, especially in hard-to-reach areas.

Routine vaccination activities have been constrained by challenges related to program management, training, health sector reform, cold chain maintenance, a largely rural population, and difficult terrain. Low routine OPV3 coverage, suboptimal AFP surveillance, and indigenous wild poliovirus transmission underscore the need for continued high quality NIDs and extra SNIDs. House-to-house vaccination activities should continue to reach children residing in hard-to-reach areas who have never been vaccinated. A WHO-United Nations Children's Fund (UNICEF) technical review identified the need for an increased number of mid-level surveillance officers to assist in training, clinician sensitization, and supervision of active AFP surveillance in remote areas. The placement of mid-level surveillance officers in other countries has led to rapid improvement in AFP surveillance indicators.

Polio eradication priorities in Ethiopia include 1) implementing high-quality NIDs (planned for November and December 2000 and tentatively planned for 2001), 2) ensuring high-quality house-to-house vaccination campaigns in hard-to-reach areas, 3) strengthening routine vaccination, 4) strengthening facility-based active AFP surveillance to reach certification standards (nonpolio AFP rate of ≥1.0) in all zones, 5) supporting the national laboratory to attain WHO accreditation, and 6) coordinating cross-border vaccination and surveillance activities to detect possible importation of wild poliovirus from neighboring countries. Meeting these challenges will require the continued support of polio eradication partners.[§]

U: Unavailable. -:No reported cases.

*Mortality data in this table are voluntarily reported from 122 cities in the United States, most of which have populations of ≥100,000. A death is reported by the place of its occurrence and by the week that the death certificate was filed. Fetal deaths are not included.

†Pneumonia and influenza.

§Because of changes in reporting methods in this Pennsylvania city, these numbers are partial counts for the current week. Complete counts will be available in 4 to 6 weeks.

¶Total includes unknown ages.

The *Morbidity and Mortality Weekly Report (MMWR)* Series is prepared by the Centers for Disease Control and Prevention (CDC) and is available free of charge in electronic format and on a paid subscription basis for paper copy. To receive an electronic copy on Friday of each week, send an e-mail message to *listserv@listserv.cdc.gov*. The body content should read *SUBscribe mmwr-toc*. Electronic copy also is available from CDC's World-Wide Web server at *http://www.cdc.gov/mmwr* or from CDC's file transfer protocol server at *ftp://ftp.cdc.gov/pub/Publications/mmwr*. To subscribe for paper copy, contact Superintendent of Documents, U.S. Government Printing Office, Washington, DC 20402; telephone (202) 512-1800.

Data in the weekly *MMWR* are provisional, based on weekly reports to CDC by state health departments. The reporting week concludes at close of business on Friday; compiled data on a national basis are officially released to the public on the following Friday. Address inquiries about the *MMWR* Series, including material to be considered for publication, to: Editor, *MMWR* Series, Mailstop C-08, CDC, 1600 Clifton Rd., N.E., Atlanta, GA 30333; telephone (888) 232-3228.
