National Arthritis Month — May 2001

May is National Arthritis Month. Arthritis and other rheumatic conditions are the leading cause of disability in the United States, affecting approximately 43 million persons in 1997, and may affect 60 million by 2020 (1,2). Early symptom recognition is needed to achieve better control of arthritis. CDC, the Arthritis Foundation, and other organizations continue to implement the *National Arthritis Action Plan: A Public Health Strategy* (3) to promote progress toward reaching the arthritis-related national health objectives for 2010 (4).

Additional information about arthritis, National Arthritis Month, Arthritis Action Day, the National Arthritis Action Plan, and local Arthritis Foundation programs and services is available from the Arthritis Foundation, telephone (800) 283-7800, or at <http://www.arthritis.org>.*

Prevalence of Arthritis — United States, 1997

Arthritis and other rheumatic conditions (i.e., arthritis) are among the most prevalent diseases in the United States (1) and the most frequent cause of disability (2). In 1985, an estimated 35 million persons were affected by arthritis (3); in 1990 (1), a study using a broader arthritis definition estimated that 38 million were affected. To better characterize these conditions, CDC analyzed a variety of data for 1997 using common definitions from the *International Classification of Diseases, Ninth Revision, Clinical Modification* (ICD-9-CM). The findings of one such analysis in the National Health Interview Survey (NHIS) indicated that, in 1997, the prevalence of persons with arthritis had increased by approximately 750,000 per year since 1990. Findings also support earlier projections that by 2020, 60 million persons may be affected by arthritis and that the activities of 11.6 million persons may be limited by arthritis (1). More widespread implementation of existing interventions may reduce the occurrence and progression of arthritis.

Prevalence rates were estimated from NHIS, a probability sample of the civilian, noninstitutionalized population in the United States (1). Data from the 1994–1995 NHIS, the most recent surveys using ICD-9 codes for health conditions, were used to estimate the 1997 prevalence and physical activity limitations from arthritis. Estimates of arthritis prevalence rates were derived from a random sample of 36,057 (16.7%) of 218,646 respondents who were asked about the presence during the 12 months preceding the survey of any of various musculoskeletal conditions and for details of these conditions. Each condition reported was assigned an ICD-9 code. Respondents with one or more codes recommended by the National Arthritis Data Workgroup (NADW) to represent arthritis* (1) were included in the analysis. Estimated rates of activity limitations attributed to arthritis were based on responses from 218,646 respondents who were asked whether they were limited in or prevented from working, housekeeping, or performing other activities as a result of a health condition(s) and, if so, did they attribute the limitation to arthritis.

To determine the number of persons affected or limited by arthritis, age- and sex-specific prevalence rates were calculated for the civilian, noninstitutionalized population, the referent population for NHIS, and were applied to the estimated 1997 U.S. population (4) by age and sex. Rates of disease burden for the total population were generated by totaling the age- and sex-specific estimates; 95% confidence intervals were calculated using SUDAAN to account for NHIS's complex survey design.

Results of these analyses indicated that an estimated 43 million persons had arthritis in 1997. All age groups were affected, including the working-age population, and rates increased with age. Females had higher arthritis rates than males overall and for each age group (Table 1). An estimated eight million persons (3% of the U.S. population) reported arthritis as a major or contributing cause of activity limitations (Table 1). Rates increased with age and females had higher rates of activity limitations than males overall and for each age group (Table 1).

Source: 1994–1995 National Health Interview Survey.

Editorial Note: The findings in this report indicate that from 1990 to 1997, the prevalence of persons with arthritis and with activity limitations from arthritis increased substantially. Related analyses have documented 744,000 hospitalizations and 44 million ambulatory-care visits for arthritis in 1997 (5).

NADW's definition of arthritis aims to include specific conditions that would be understood as arthritis (e.g., systemic lupus erythematosus, infectious arthritis, and carpal tunnel syndrome). Because many persons with arthritis may not consult a physician for their condition (6), NHIS self-reported data may provide a more accurate estimate of the prevalence and impact of arthritis than medical encounter-based data. In addition, the data allow an understanding of the time trends in arthritis because the case definitions and survey methods are the same as the 1990 estimates (7).

The findings in this study are subject to at least four limitations. First, the estimates used self-reported data that were not confirmed by a physician. Second, to estimate the total burden of disease, the analysis used rates based on surveys of the civilian, noninstitutionalized population, which represents 98% of the total U.S. population but excluded certain groups (e.g., the institutionalized elderly) that are likely to have different

Arthritis — Continued

rates. Third, data used intercensal projections for denominators; these projected denominators may be inaccurate. Finally, rate estimates were assumed unchanged from 1995 to 1997; however, this may be reasonable because age- and sex-specific prevalence rates were virtually unchanged from 1990 (1).

Further studies are needed to define the prevalence of specific types of arthritis, to provide direct measures of arthritis prevalence, to determine the financial and societal impact of arthritis, and to quantify the impact of arthritis at the state level and in health-care systems. Future analyses of NHIS data will need to accommodate the change from ICD-9-based code assignment of conditions to a symptom-based approach to the case definition of arthritis.

Interventions are available that may reduce the occurrence and progression of arthritis. Measures to reduce obesity and avoid occupational and sports injuries can be expected to reduce the risk for osteoarthritis of the knees (7). Other interventions include supervised exercise programs, weight loss, and self-education courses such as the Arthritis Self-Help Course, which has been shown to reduce pain and physician visits (8). Unless such interventions are implemented quickly and widely, national projections suggest that arthritis will become a larger public health problem (1). Health-care providers, policymakers, and the public health community need to plan for the impact of this growth. CDC funds 37 state health departments to develop or enhance prevention programs and to identify new approaches to improving the quality of life for persons affected by arthritis (9).

Trends in Blood Lead Levels Among Children — Boston, Massachusetts, 1994–1999

Data from the National Health and Nutrition Examination Survey and national childhood blood lead surveillance data from 19 states indicated that average blood lead levels (BLLs) in young children decreased during the late 1990s (1–3). The proportion of children tested who had BLLs ≥ 10 $\mu\text{g}/\text{dL}$ declined from 10.5% in 1996 to 7.6% in 1998, although the proportion was higher in certain counties (3). To determine whether a similar decline had occurred in Boston, Massachusetts, where a high proportion of children are tested each year, and whether any changes were similar in high- and low-risk neighborhoods, CDC, in collaboration with the Boston Childhood Lead Poisoning Prevention Program (BCLPPP) performed an analysis of BLLs among children aged 6–72 months in Boston during 1994–1999. The results indicate that BLLs in Boston declined during this period, but because of the geographic variation in lead exposure, continued surveillance will be necessary to eliminate childhood lead poisoning.

Private laboratories are mandated by Massachusetts law to report all blood lead test results to the state laboratory. BCLPPP receives all blood lead test results for Boston residents from the state laboratory. Massachusetts lead screening regulations require that health-care providers screen children at age 9–12 months and annually up to age 48 months. Children at high risk for lead poisoning are screened every 6 months during ages 6 months–3 years and annually from ages 3–6 years. The proportion of children tested who had BLLs ≥ 10 $\mu\text{g}/\text{dL}$ and ≥ 20 $\mu\text{g}/\text{dL}$ by fiscal year (FY) from July 1, 1993, through June 30, 1999, was computed. Children were counted once in each FY in which they had at least one blood lead test, and the highest test result in a given FY was considered in the analysis. Because sample contamination of a capillary test can result in a slight overestimation of BLLs, only tests performed on venous samples with BLLs ≥ 10 $\mu\text{g}/\text{dL}$ were considered in the numerator, and tests using both venous and capillary samples were used in the denominator (4,5). Massachusetts Institute for Social and Economic Research data were used to estimate the population of children aged <6 years for 1994 and 1998 (4). U.S. census data from 1990 were used to characterize 16 Boston neighborhoods by ZIP code according to factors that may indicate risk for lead exposure (e.g., percentage of pre-1950 housing, minority children, and children aged <6 years living in poverty). Housing parcel information was obtained from tax assessor data.

The number of children aged 6–72 months screened annually in Boston declined 23%, from 35,304 (73.3% of the population aged <6 years) in 1994 to 27,233 (61.6% of population aged <6 years) in 1999 (Figure 1). However, screening among children aged 9–48 months remained high (82% during FY 1999).

During 1994–1999, the overall prevalence of children with BLLs ≥ 10 $\mu\text{g}/\text{dL}$ declined 45%, from 9.3% (3265) to 5.1% (1398). The prevalence of children with BLLs ≥ 20 $\mu\text{g}/\text{dL}$ declined 66%, from 1.5% (545) to 0.5% (140) (Figure 1). Neighborhoods with prevalence rates in the upper tertile in 1994 had a higher percentage of children living in poverty, Spanish-speaking households, and vacant parcels than neighborhoods with lower prevalence rates (Table 1). Overall, about two thirds of houses were built before 1950, and no substantial differences were found in the proportion of houses built before 1950 between the highest and lowest risk neighborhoods. The prevalence of elevated BLLs declined from 1994 to 1999 in all 16 neighborhoods, with the highest absolute average decline

Blood Lead Levels — Continued

FIGURE 1. Number of children tested for blood lead and prevalence of these children with elevated blood lead levels (BLLs), by year — Boston, Massachusetts, 1994–1999**TABLE 1. Risk levels for elevated blood lead levels (BLLs) in 16 neighborhoods, by risk factor — Boston, Massachusetts, 1994–1999**

Neighborhood prevalence tertile*	Average prevalence of BLLs $\geq 10 \mu\text{g/dL}$		Absolute change in average prevalence of BLLs $\geq 10 \mu\text{g/dL}$ 1994–1999	% children aged <6 years with BLLs $\geq 10 \mu\text{g/dL}$ 1999	Average % children aged <6 years living below poverty level	Average % pre-1950 housing	% vacant parcels	% minorities	Average % Spanish-speaking households
	1994	1999							
High	11.0	6.2	4.8	79.8%	31.1%	67.6%	63.0%	21.0%	12.1%
Medium	5.5	3.0	1.5	18.6%	24.8%	65.2%	25.0%	9.4%	8.4%
Low	2.5	1.2	1.3	1.6%	22.5%	66.2%	12.0%	3.5%	4.4%

* Neighborhood risk was based on the 1999 average prevalence of BLLs $\geq 10 \mu\text{g/dL}$ in 16 neighborhoods.

(4.8%) in neighborhoods with the highest prevalence in 1994. In 1999, six high-risk neighborhoods accounted for 80% of children with elevated BLLs, approximately the same as in 1994 (83%).

The decline in prevalence of elevated BLLs during 1994–1999 was similar across age groups: 51% among children aged <12 months, 42% among children aged 12–36 months, and 46% among children aged 36–72 months.

Reported by: S Franco, MS, Childhood Lead Poisoning Prevention Program, Boston Public Health Commission, Boston, Massachusetts. Lead Poisoning Prevention Br, Div of Environmental Hazards and Health Effects, National Center for Environmental Health, CDC.

Blood Lead Levels — Continued

Editorial Note: The findings in this report indicate that the prevalence of elevated BLLs in Boston declined consistently during 1994–1999, similar to declines reported from 19 states (3). Building of new houses and remodeling of older houses that removed lead painted building components, such as windows, may have contributed to this decrease (6). In addition, under the Massachusetts Lead Law*, BCLPPP has required property owners to correct lead paint hazards in dwellings occupied by children aged <6 years. Since 1985, approximately 6800 de-leading code enforcement activities have occurred in Boston, and the law has encouraged many additional property owners to comply with de-leading activities (BCLPPP, unpublished data, 2000).

Although BLLs have declined in all Boston neighborhoods, levels remained higher in 1999 in the areas with the highest levels in 1994. These high-risk neighborhoods are characterized by higher proportions of minority children, children living in poverty, and vacant properties; a high proportion of old housing, likely to have leaded paint, is found in all neighborhoods. Low socioeconomic status and associated deterioration of older housing are major contributors to lead exposure in Boston (7).

The findings in this report are subject to at least four limitations. First, reporting of blood lead test results varied among different laboratories; therefore, results may not be uniform. Second, children at high risk for blood lead poisoning also may have high screening rates. Third, this analysis does not include lead exposure measures associated with the children in the study; as a result, the prevalence rates in the population screened may not be representative of all children in Boston. Finally, the use of older housing and demographic information (i.e., census and tax assessor data) may not reflect changes in some Boston neighborhoods.

Approximately 1300 children in Boston are identified annually with BLLs ≥ 10 $\mu\text{g/dL}$, levels high enough to adversely affect cognitive development and behavior. One of the national health objectives for 2010 is to eliminate childhood lead poisoning (8). Because of the substantial geographic variation in lead exposure, continued use of blood lead data for surveillance purposes will be essential in Boston and other jurisdictions to focus resources on high-risk neighborhoods and to achieve the health objective.

National Estimates of Nonfatal Injuries Treated in Hospital Emergency Departments — United States, 2000

On July 1, 2000, the Consumer Product Safety Commission's (CPSC) National Electronic Injury Surveillance System (NEISS) was expanded to collect data on all types and external causes of nonfatal injuries and poisonings treated in U.S. hospital emergency departments (EDs). This augmented system, called NEISS All Injury Program (NEISS-AIP), is a collaborative effort between CDC's National Center for Injury Prevention and Control and CPSC. This report presents annualized national estimates using NEISS-AIP data obtained during July 1–September 30, 2000, which indicate that approximately 31,000,000 persons were treated for nonfatal injuries in EDs in 2000. Although most of the injuries were unintentional, an estimated 1,973,000 were violence-related. Data from NEISS-AIP can be used for monitoring temporal trends in nonfatal injuries by mechanism and intent of injury.

NEISS-AIP data were collected from 66 of the 100 NEISS hospitals, which were selected as a stratified probability sample of all hospitals in the United States and its territories with a minimum of six beds and a 24-hour ED (1,2). The 66 NEISS-AIP hospitals are a nationally representative sample of U.S. hospital EDs. NEISS-AIP hospitals provide data on approximately 600,000 injury- and consumer product-related ED cases each year. Data from these cases are weighted by the inverse of the probability of selection to provide national estimates (1). Annualized estimates were based on weighted data for 126,547 nonfatal injury-related ED visits during July 1–September 30, 2000. Each sample was weighted by four and then these adjusted weights were added to provide annualized estimates for the overall population and population subgroups (i.e., age, sex, and race/ethnicity*). SUDAAN was used to account for the complex sample design (1).

Nonfatal injuries and poisonings were defined as bodily harm resulting from acute exposure to an external force or substance (i.e., mechanical, thermal, electrical, chemical, or radiant) and near drowning, including unintentional and violence-related causes. Cases were excluded if 1) the principal diagnosis was an illness, pain only, psychological harm (e.g., anxiety and depression) only, contact dermatitis associated with exposure to consumer products (e.g., body lotions, detergents, and diapers) and plants (e.g., poison ivy), or unknown; or 2) the ED visit was for adverse effects of therapeutic drugs or of surgical and medical care (3).

All injuries were classified for intent of injury (i.e., unintentional, assault, self harm, and legal intervention) and mechanism of injury (i.e., fall, struck by/against, motor-vehicle-occupant-related incident, cut/pierce, and fire/burn) (4). Unintentional included unintended injuries and injuries in which no indication of intent to harm was documented in the ED record. Assault included suspected and confirmed injuries from interpersonal violent events (e.g., injuries to victims, innocent bystanders, police, and perpetrators). Self harm included suspected and confirmed intentionally self-inflicted injuries. Legal intervention included injuries inflicted by police or other legal authorities (e.g., security guards) while acting in the line of duty. The mechanism of injury represents the precipitating mechanism that initiated the chain of events leading to the injury, which is similar

*On the ED record, often only one entry is available for race or ethnicity. The classification scheme for this report assumed that most white Hispanics probably were recorded on the ED record as Hispanics and most black Hispanics probably were recorded as black.

Nonfatal Injuries — Continued

to the underlying cause for injury-related death. Mechanisms of injury were classified by trained coders into recommended major external cause-of-injury groupings (3,5) using definitions consistent with *International Classification of Diseases, Ninth Revision, Clinical Modifications* (ICD-9-CM) external cause coding guidelines (6). Because of limited resources, ICD-9-CM external cause-of-injury codes were not assigned.

During 2000, persons with nonfatal injuries were treated in EDs at an estimated rate of 11,188 per 100,000 population. The nonfatal injury rate was approximately 40% higher for males than for females (Table 1). Males aged 15–19 years had the highest nonfatal injury rate (20,528 per 100,000 population) (Table 1). Of the estimated 31,000,000 nonfatal injuries, 93.6% were unintentional and the remaining 6.4% were violence-related, including assaults (5.5%), intentional self harm (0.7%), and legal interventions (0.2%) (Table 2). Falls were the leading cause of unintentional nonfatal injuries, accounting for an estimated 7,021,000 (24.4%) of unintentional injury-related ED visits. An estimated 3,299,000 persons were injured as an occupant in a motor vehicle (Table 2), of which 95.2% were traffic-related. Injuries to motor-vehicle occupants were the leading cause of unintentional nonfatal injury-related ED visits for females aged 15–24 years. The nonfatal injury rate for pedal cyclists was 2.9 times higher for males than for females (Table 2). An estimated 389,000 persons were treated in EDs for dog bites (Table 2).

Of an estimated 1,973,000 violence-related nonfatal injuries, 66% were physical assaults that included being hit with an object or by another person (Table 2). Sexual assault was the fourth leading cause of violence-related, nonfatal injury-related ED visits; the nonfatal rate of sexual assault for females was 4.8 times higher than that for males (Table 2). Approximately 150,000 persons were treated in EDs for poisoning-related suicide attempts and the rate of intentionally self-inflicted, nonfatal poisonings for females was 1.6 times that for males (Table 2).

Reported by: Office of Statistics and Programming, National Center for Injury Prevention and Control, CDC.

Editorial Note: The findings in this report indicate that, in 2000, approximately 10% of U.S. residents were treated for nonfatal injuries in EDs. On the basis of NEISS-AIP and National Vital Statistics System data (7), for every injury-related death in the United States, approximately 200 persons were treated for nonfatal injuries in EDs. Most (93.6%) of these injuries were unintentional; however, approximately 2 million persons were treated for violence-related injuries. NEISS-AIP will provide a national data source for further characterizing these injuries by unintentional and violence-related causes and helping to identify those at risk.

NEISS-AIP will provide additional data on the characteristics and circumstances of injuries that are treated in EDs. In addition to age, race/ethnicity, sex, intent of injury, and mechanism of injury, data are being collected on principal diagnosis, primary body part affected, locale where the injury occurred, work-relatedness, consumer products involved, and disposition at ED discharge. For transport-related injuries, data are being collected on traffic-relatedness and on motor-vehicle occupant status (e.g., driver, passenger, boarding, and alighting) at the time of the injury. For assaults, data are being collected on the relationship of the perpetrator to the injured person (e.g., spouse/partner, parent, other relative, friend, and stranger) and the context (e.g., altercation, robbery, sexual assault, drug-related, and gang-related). In addition, on the basis of information in the ED record, a brief narrative is being recorded that provides further details about the circumstances of the incident.

Nonfatal Injuries — Continued

Annualized national estimates of NEISS-AIP data for July 1–September 30, 2000, are comparable to estimates based on other surveys. Data for 1998 from the National Hospital Ambulatory Medical Care Survey (NHAMCS), which collects data on all types of ED visits and focuses primarily on health-care utilization, identified an average annual estimate of 37,111,000 injury-related ED visits (8). NHAMCS used an injury definition similar to that of NEISS AIP. However, the NHAMCS estimate includes both initial ED visits and revisits for the same injury; the NEISS-AIP estimate includes only initial ED visits. Data from a 3-month NEISS All Injury Pilot Study conducted during May 1–July 31, 1997, of a nationally representative sample of 21 NEISS hospitals identified an annualized estimate of 29,060,000 injuries (9). The distributions of injuries by intent and mechanism of injury were similar among all three data sources. For example, the percentage of injury-related ED visits that were violence-related was 5.2% for NHAMCS, 5.6% for the NEISS All Injury Pilot Study, and 6.4% for NEISS-AIP. The percentage of violence-related cases for NEISS-AIP might be expected to be highest because data were obtained for ED visits during July–September when assault rates are higher than during other months of the year (10).

The findings in this report are subject to at least three limitations. First, this system provides only national estimates and does not allow for estimates by region, state, or local jurisdiction. Second, data are based solely on information provided in the ED record and are not linked to criminal justice, police reports, or other data sources to supplement or verify the cause and intent of injury. Finally, because the estimates were derived from 3 months of data, they do not account for cause-specific seasonal differences in the number of injuries (10).

Hospital audits conducted by CPSC indicate that NEISS hospital coders identify approximately 90% of all reportable product-related cases (A. McDonald, CPSC, personal communication, 2001). NEISS also has the capacity to conduct special studies to collect more details about specific types and causes of injury, and in-depth follow-up interviews for case studies of injury circumstances and consumer product involvement.

U: Unavailable. --:No reported cases.

*Mortality data in this table are voluntarily reported from 122 cities in the United States, most of which have populations of ≥100,000. A death is reported by the place of its occurrence and by the week that the death certificate was filed. Fetal deaths are not included.

[†]Pneumonia and influenza.

[‡]Because of changes in reporting methods in this Pennsylvania city, these numbers are partial counts for the current week. Complete counts will be available in 4 to 6 weeks.

[†]Total includes unknown ages.

The *Morbidity and Mortality Weekly Report (MMWR)* Series is prepared by the Centers for Disease Control and Prevention (CDC) and is available free of charge in electronic format and on a paid subscription basis for paper copy. To receive an electronic copy on Friday of each week, send an e-mail message to listserv@listserv.cdc.gov. The body content should read *SUBscribe mmwr-toc*. Electronic copy also is available from CDC's World-Wide Web server at <http://www.cdc.gov/mmwr> or from CDC's file transfer protocol server at <ftp://ftp.cdc.gov/pub/Publications/mmwr>. To subscribe for paper copy, contact Superintendent of Documents, U.S. Government Printing Office, Washington, DC 20402; telephone (202) 512-1800.

Data in the weekly *MMWR* are provisional, based on weekly reports to CDC by state health departments. The reporting week concludes at close of business on Friday; compiled data on a national basis are officially released to the public on the following Friday. Address inquiries about the *MMWR* Series, including material to be considered for publication, to: Editor, *MMWR* Series, Mailstop C-08, CDC, 1600 Clifton Rd., N.E., Atlanta, GA 30333; telephone (888) 232-3228.

All material in the *MMWR* Series is in the public domain and may be used and reprinted without permission; citation as to source, however, is appreciated.
