National Colorectal Cancer Awareness Month — March 2003

March is National Colorectal Cancer Awareness Month. This national health observance serves to increase public awareness about the disease burden of colorectal cancer (i.e., cancer of the colon or rectum) and to encourage adults aged ≥ 50 years to reduce their risk through regular screening examinations. Colorectal cancer is the second leading cause of cancer-related death in the United States. During 2003, an estimated 147,500 new cases and 57,100 deaths will occur (1). However, despite recommendations for screening, many persons who are at risk for colorectal cancer are not being screened.

CDC's Colorectal Cancer Prevention and Control Initiative raises public awareness through the "Screen for Life" campaign, which communicates the importance of regular screening for adults aged ≥50 years, and "A Call to Action," an education program designed to raise health-care providers' awareness and knowledge about prevention and early detection. CDC also works with partners to support the National Colorectal Cancer Roundtable, a coalition of organizations that educates health-care providers and the public about screening. Finally, CDC funds comprehensive cancer control programs to integrate a full range of cancer control activities, improve community-based education and health promotion, and target at-risk populations.

Additional information about colorectal cancer awareness and provider training materials are available from CDC at http://www.cdc.gov/cancer/screenforlife and http://www.cdc.gov/cancer/colorctl/calltoaction.

Colorectal Cancer Test Use Among Persons Aged <u>></u>50 Years — United States, 2001

Colorectal cancer is the second leading cause of cancerrelated death in the United States (1). The lifetime risk for having colorectal cancer diagnosed is 6% (2). Screening measures decrease the incidence and mortality of colorectal cancer by detecting early disease and removing precancerous lesions (3). The U.S. Preventive Services Task Force recommends routine cancer screening for U.S. adults aged \geq 50 years with one or a combination of the following screening options: annual home fecal occult blood testing (FOBT), sigmoidoscopy every 5 years, colonoscopy every 10 years, or double contrast barium enema every 5 years (3). To estimate rates and evaluate trends for colorectal cancer test use among U.S. adults aged ≥50 years, CDC analyzed data from the 2001 Behavioral Risk Factor Surveillance System (BRFSS) on the use of FOBT and sigmoidoscopy/colonoscopy and compared the data for 2001 with those for 1997 and 1999. This report summarizes the results of that analysis, which indicate that despite small increases in the self-reported use of colorectal cancer tests, screening rates remain low. Efforts to increase awareness and encourage regular colorectal cancer screening should continue.

Notifiable Disease Morbidity and 122 Cities Mortality Data Robert F. Fagan Deborah A. Adams Felicia J. Connor Lateka Dammond Patsy A. Hall Pearl C. Sharp BRFSS is a state-based, random-digit-dialed telephone survey of the civilian, U.S. noninstitutionalized population aged \geq 18 years. In 2001, all 50 states, the District of Columbia, Puerto Rico, the Virgin Islands, and Guam participated in BRFSS. Respondents aged \geq 50 years, the age group for which colorectal cancer screening is recommended, were asked whether they ever had used "a special kit at home to determine whether the stool contains blood" (FOBT), whether they ever had "a tube inserted through the rectum to view the bowel for signs of cancer or other health problems" (sigmoidoscopy/colonoscopy), and when these tests were last performed. For this report, both sigmoidoscopy and colonoscopy are described as "lower endoscopy."

Previous reports have examined lower endoscopic surveillance within 5 years as a measure of compliance with screening guidelines (4). Because BRFSS could not differentiate between sigmoidoscopy and colonoscopy, for this survey, the surveillance period was 10 years to include those undergoing colonoscopy. Any respondents reporting lower endoscopy within 10 years were considered to have been screened within the recommended period. Percentages were estimated for persons aged \geq 50 years who had reported FOBT ever and within the 12 months preceding the survey, lower endoscopy ever and within 5 and 10 years preceding the survey, and FOBT within 12 months and/or lower endoscopy within 10 years preceding the survey.

For the 2001 BRFSS, the median state response rate was 51.1% (range: 33.3%–81.5%) using the CASRO method (5). A total of 87,729 persons aged \geq 50 years responded. Responses coded as "don't know/unsure" or "refused" were excluded from analysis (3%–4%). Proportions, standard errors, and 95% confidence intervals were calculated by using SAS v8 and SUDAAN. Data were weighted to the age, sex, and race/ ethnicity distribution of the adult population in each state by using intercensal estimates and age standardized to the 2001 BRFSS population. Estimates for the percentage of adults aged \geq 50 years who self-reported receiving either FOBT within 12 months or lower endoscopy within 5 years (1997 and 1999 surveys did not include responses within 10 years) were compared for 1997, 1999, and 2001.

In 2001, an estimated 44.6% of adults aged \geq 50 years had ever had FOBT, and 47.3% had ever had a lower endoscopy. An estimated 23.5% had FOBT within 12 months; 43.4% had lower endoscopy within 10 years; 53.1% had one or both tests within the periods described (Table). By state, the estimates for FOBT within 12 months ranged from 6.8% in Alabama to 34.5% in Maine; for lower endoscopy within 10 years, estimates ranged from 28.4% in the Virgin Islands to 58.5% in Minnesota. The estimates for reporting either FOBT within 12 months and/or lower endoscopy within 10 years varied by state from 42.2% in Oklahoma to 65.3% in the District of Columbia (Figure 1).

The percentage of persons aged \geq 50 years who had received FOBT within 12 months was 19.4% in 1997, 20.4% in 1999, and 23.5% in 2001. For lower endoscopy within 5 years, the proportions were 29.9%, 33.3%, and 38.7%, respectively (Figure 2).

Reported by: L Seeff, MD, M Nadel, PhD, D Blackman, PhD, Div of Cancer Prevention and Control, National Center for Chronic Disease Prevention and Health Promotion; LA Pollack, MD, EIS Officer, CDC.

Editorial Note: The findings in this report indicate that colorectal cancer test use among U.S. adults remains low. Approximately half of U.S. adults aged \geq 50 years have not received the recommended screening.

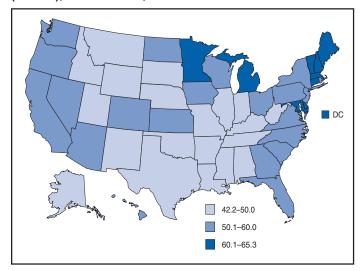

TABLE. Percentage of adults aged ≥50 years who reported receiving a fecal occult blood test (FOBT) within 12 months preceding survey and/or lower endoscopy within 5 and 10 years preceding survey, by test type — Behavioral Risk Factor Surveillance System (BRFSS), United States, 2001*

Test	%	(95% Cl†)
FOBT within 12 mos	23.5	(<u>+</u> 0.5)
Lower endoscopy within 5 yrs	38.7	(<u>+</u> 0.5)
Lower endoscopy within 10 yrs	43.4	(<u>+</u> 0.6)
FOBT within 12 mos and/or		
lower endoscopy within 10 yrs	53.1	(<u>+</u> 0.6)

* Age-adjusted to the 2001 BRFSS population.

FIGURE 1. Percentage of adults aged \geq 50 years who reported receiving a fecal occult blood test within 12 months preceding survey and/or lower endoscopy within 10 years preceding survey, by state — Behavioral Risk Factor Surveillance System (BRFSS), United States, 2001*

* Age-adusted to the 2001 BRFSS population.

FIGURE 2. Percentage of adults aged \geq 50 years who reported receiving a fecal occult blood test (FOBT) within 12 months preceding survey and/or lower endoscopy within 5 years* preceding survey, by test type and year — Behavioral Risk Factor Surveilliance System (BRFSS), United States, 1997– 2001[†]

*1997 and 1999 surveys did not include responses within 10 years. [†]Age-adusted to the 2001 BRFSS population.

The findings in this report are subject to at least five limitations. First, the percentages reported overestimate colorectal cancer screening rates because 1) BRFSS could not differentiate test use specifically for screening from tests performed for diagnostic purposes and 2) persons who received sigmoidoscopy outside the recommended 5-year screening interval, but within 10 years, were considered compliant with screening guidelines. As a result, colorectal cancer screening rates are probably lower than the estimates in this report. Second, BRFSS excludes residents of institutions and persons who do not own telephones. Third, estimates from BRFSS were based on self-reports and were not validated; however, previous studies document moderate-to-good concordance between the selfreporting of colorectal cancer tests and medical records (6, 7). Fourth, the response rate of 51.1% is low and has been low in previous years (62.1% in 1997 and 55.2% in 1999) (5). Health-care-seeking behaviors might differ among respondents and nonrespondents. Finally, data on the use of barium enema, another option for colorectal cancer screening, were not provided in BRFSS. However, barium enema is recommended less often than FOBT or sigmoidoscopy (8).

Colorectal cancer test screening rates are much lower than breast and cervical cancer test screening rates (mammography and Papanicolaou smear, respectively) (9). This shortfall warrants increased public and health-care provider awareness and supportive health-care systems that emphasize and ensure accessibility to colorectal cancer screening. In July 2001, Medicare reimbursement was approved for colonoscopy screening for persons with average risk for colorectal cancer; this measure might increase future screening rates.

To promote colorectal cancer screening, CDC will launch its annual "Screen for Life: A National Colorectal Cancer Awareness Campaign" (http://www.cdc.gov/cancer/ screenforlife), which encourages persons aged ≥ 50 years to discuss screening for colorectal cancer with their doctor and to select appropriate test(s). For health-care providers, CDC also has produced an education program, "A Call to Action: Prevention and Early Detection of Colorectal Cancer" (http:/ /www.cdc.gov/cancer/colorctl/calltoaction). In addition, CDC has supported a measure of colorectal cancer screening for the Health Plan Employer Data and Information Set (HEDIS), a set of standardized performance measures that permits comparison of managed care organizations. The measure has been approved provisionally for inclusion in HEDIS in 2004. To address issues related to mass screening, CDC's Survey of Endoscopy Capacity will examine the national distribution of lower endoscopes and trained health-care providers.

Donated Television Airplay of Colorectal Cancer Education Public Service Announcements — United States, 1999–2002

To help communicate the importance of colorectal cancer (CRC) screening, in 1999, the U.S. Department of Health and Human Services (DHHS) launched the "Screen for Life: National Colorectal Cancer Action Campaign" (SFL) (http:// www.cdc.gov/cancer/screenforlife) (1) as one of many strategies addressing the prevention and early detection of CRC. As a central part of this campaign, public service announcements (PSAs) were developed to take advantage of the influence and reach of television to encourage Americans aged \geq 50 years to get tested for CRC. This report summarizes an assessment of donated television airplay that SFL PSAs received during March 1999-February 2002. According to data obtained from Arbitron Inc., a research firm that monitors broadcast media in the United States, SFL PSAs were broadcast 41,624 times, amounting to approximately \$4.3 million in donated television airtime. As DHHS and others promote CRC screening, CDC will continue to release and track airplay of SFL PSAs and examine the collective influence that SFL and other educational efforts and strategies have on CRC screening rates in the United States.

CDC, in collaboration with the Centers for Medicare & Medicaid Services, developed and launched SFL in March 1999 and released new campaign materials in July 2000 (Phase II) and March 2001 (Phase III). Each campaign phase builds upon the previous one and includes these messages: CRC is the second leading cancer killer, screening saves lives, and screening can find precancerous polyps that can be removed before they turn cancerous. To track campaign airplay, CDC uses the 24-hour monitoring services of Arbitron's Sigma system, which monitors PSA airplay on approximately 1,000 television stations in all 210 U.S. Designated Market Areas[®] (DMAs)* and approximately 75 regional and national cable channels. The Sigma system tracks airplay by embedding an electronic code in the video signal of PSAs before their distribution to television stations nationwide.

When a PSA airs, monitoring devices in that DMA detect the code and record the broadcast time, date, day of week; television station call letters; and PSA name and length. Arbitron links these data to estimates of the commercial dollar value of each airplay and the number of times the PSA was seen, known as "audience impressions." The data are transmitted monthly to CDC for analysis.

^{*} As defined by Nielsen Media Research (http://www.nielsenmedia.com/ DMAs.html).

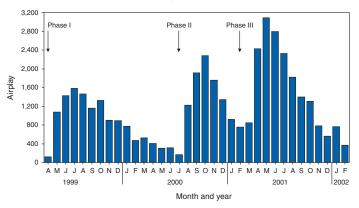

During March 1999-February 2002, the PSAs were broadcast nationwide 41,624 times, resulting in an estimated 749 million audience impressions worth an estimated \$4.3 million. Phase II of the campaign had the highest number of audience impressions, and Phase III had the most airplay and highest value (Table). During each phase, total airplay for SFL PSAs peaked within 3-4 months of launch, then slowly decreased. Each phase has been associated with a higher airplay peak than the previous phase (Figure 1). The percent of DMAs airing the PSAs also increased with each phase. During the 3year period, 94% of DMAs played the PSAs at least once, and airplay ranged from 1 to 4,578 per DMA (Figure 2).

Patterns of airplay over the three phases indicate that 17,061 (41%) of the total 41,624 SFL PSA plays occurred during daytime (6:00 a.m.-7:59 p.m.); 2,144 (5%) occurred during prime time (8:00 p.m.-10:59 p.m.); and 22,419 (54%) occurred overnight (11:00 p.m.- 5:59 a.m.). The airplay that occurred during daytime accounted for 415 million (55%) of total audience impressions. Prime time airplay accounted for 97 million (13%) total audience impressions. Overnight airplay accounted for 236 million (32%) of total estimated audience impressions.

During each campaign phase, an increasing number of states incorporated SFL materials, including PSAs, into their CRC prevention programs. By Phase III, 23 states had adopted SFL. To assess whether CRC burden influenced the adoption of SFL, CDC compared the latest CRC mortality rates (1999) (2) in states that participated in SFL in 2002 with those that did not participate. No statistically significant differences were found. A comparison of airplay in participating and nonparticipating states is planned.

Editorial Note: Media campaigns alone rarely change behaviors; however, when included as part of a multicomponent intervention strategy, they have a strong synergetic effect. Used in this manner, media campaigns can reach large numbers of people quickly, raise awareness about health issues, and reinforce communication between patients and health-care providers (3-7). The findings in this report indicate that the SFL campaign has benefitted from the donation of a substantial amount of airplay by television stations nationwide.

As the campaign progressed, each phase achieved an increasingly higher peak of airplay. This trend might be associated with several factors, including increased national attention to CRC as a major public health issue, designation by the U.S. Congress in 2000 of March as "National Colorectal Cancer Awareness Month," and increased state and local educational efforts. All these factors might have helped influence public attitudes and contributed to the increases in CRC screening rates observed in some states (8). However, additional research would be necessary to gauge the specific contribution of PSAs to these increases.

The findings in this report are subject to at least two limitations. First, Arbitron's Sigma system, the only PSA tracking system available, bases estimates of dollar value and audience impressions on advertising figures used by the commercial sector. These figures change weekly and are set according to a complex and proprietary system of perceived market value and demand. Second, the Sigma system provides a conservative estimate of airplay because it does not monitor many channels offered through local cable or satellite services.

Data analysis using the Sigma system and Geographic Information Systems technology can be useful in identifying media markets that have little or no airplay, allowing state and local health officials to increase promotion of SFL. CDC and its partners will continue to release new phases of SFL, including PSAs, as part of a multicomponent approach to prevention and early detection of CRC.

Poisoning by an Illegally Imported Chinese Rodenticide Containing Tetramethylenedisulfotetramine — New York City, 2002

Illegally imported foreign products can result in domestic exposures to unusual toxic chemicals, and health-care providers might not be able to provide appropriate therapy because the chemical ingredients might not be listed or recognized even after translation of the product label. This report describes the first known case in the United States of exposure to a Chinese rodenticide containing the toxin tetramethylenedisulfotetramine (TETS), a convulsant poison. The report of this investigation highlights the need to prevent such poisonings through increased public education, awareness, and enforcement of laws banning the importation of illegal toxic chemicals.

On May 15, 2002, a previously healthy female infant aged 15 months living with her family in New York City was found by her parents to be playing with a white rodenticide powder that they had brought from China and applied in the corner of their kitchen. After 15 minutes, the child had generalized seizures and was taken to an emergency department. Her initial blood glucose level was 108 mg/dL (normal range: 80– 120 mg/dL). Despite aggressive therapy with lorazepam, phenobarbital, and pyridoxine, she had intermittent generalized seizure activity for 4 hours and required intubation.

After 3 days, the infant was extubated successfully but appeared to have multiple neurologic deficits, including absence seizures and possibly cortical blindness. Continuous electroencephalogram monitoring, performed during the initial hospitalization, revealed multiple epileptogenic foci. The infant was discharged in June; as of November 5, the infant remained severely developmentally delayed and was on valproic acid therapy for seizure control.

Translation of the rodenticide package labeling from Chinese to English did not clarify its contents (Figure). A search of the China National Poison Control Center's (NPCC) website for rodenticides suggested that the ingredients might have included sodium monofluoroacetate, fluoroacetamide, tetramethylenedinitrosotetramine, or strychnine. However, an initial laboratory analysis was negative for sodium fluoroacFIGURE. Package of Chinese rodenticide implicated in the poisoning of a female infant aged 15 months — New York City, 2002

Photo/New York City Poison Control Center

etate, fluoroacetamide, bromethalin, strychnine, 1,3-difluoro, 2-propanol, and carbamate insecticides.

On September 14, a snack shop owner in China poisoned food in a competitor's snack shop with a rodenticide identified as Dushuqiang, resulting in 38 deaths. Although Dushuqiang, which contains TETS, has been banned for sale since the mid-1980s, it is still widely available in China. Following news reports of this incident, the New York City Poison Control Center conducted additional laboratory testing of the product associated with the poisoning in New York City and confirmed TETS in the product by gas chromatography-mass spectrometry (GC-MS) (1). TETS concentration was 6.4% weight/weight [w/w] in one rodenticide packet and 13.8% w/w in another. **Reported by:** F Barrueto Jr, MD, LS Nelson, MD, RS Hoffman, MD, New York City Poison Control Center; MB Heller, PhD, Public Health Laboratory, General Toxicology and Environmental Science Laboratory, New York City Dept of Health and Mental Hygiene; PM Furdyna, New York State Div of Environmental Conservation; RJ Hoffman, MD, Div of Toxicology, Maimonides Medical Center, New York, New York. KS Whitlow, DO, MG Belson, MD, AK Henderson, PhD, Div of Environmental Hazards and Health Effects, National Center for Environmental Health, CDC.

Editorial Note: TETS is a little-known, often unrecognized, and highly lethal neurotoxic rodenticide that once was used widely. An odorless, tasteless, and water-soluble white crystalline powder that acts as a γ -amino butyric acid (GABA) antagonist (China Center for Disease Control and Prevention [CDC], unpublished data, 2002), TETS, like picrotoxin, binds noncompetitively and irreversibly to the GABA receptor on the neuronal cell membrane and blocks chloride channels. The most common routes of exposures are through ingestion and inhalation (China CDC, unpublished data, 2002). TETS is not registered by the U.S. Environmental Protection Agency for use in the United States, and its importation, manufacture, and use in the United States are illegal.

TETS meets criteria for inclusion in the list of extremely hazardous pesticides maintained by the World Health Organization (WHO) and is more lethal than WHO's most toxic registered pesticide, sodium fluoroacetate (2). Multiple large intentional and unintentional exposures in China have demonstrated the human toxicity of TETS (1). The dose at which TETS kills 50% of mammals (LD50) is 0.1–0.3 mg/kg; a dose of 7.0–10.0 mg is considered lethal in humans. TETS is potentially 100 times more toxic to humans than potassium cyanide and might be a more powerful human convulsant than strychnine (3).

The most recognizable clinical signs after a TETS exposure are refractory seizures. Other potentially serious signs include coma and possible electrocardiogram evidence of ischemia (China CDC, unpublished data, 2002). Symptoms typically begin within 30 minutes after exposure and can begin as long as 13 hours after exposure. Severe poisonings are usually fatal within 3 hours (Sun C, China NPCC, personal communication, 2002). TETS intoxication is determined rapidly from history and clinical suspicion. Laboratory identification, although not clinically useful in an acute presentation, is accomplished by several methods, including gas chromatography (GC) with nitrogen-phosphorous detection, GC with flame photometric detection, and GC-MS (1,4,5). TETS is registered with the Chemical Abstract Service Division of the American Chemical Society as number 80-12-6, molecular weight 240, and chemical formula of $C_4H_8N_4O_4S_2$. Every attempt should be made to identify this chemical if it is suspected.

No proven antidote exists for TETS poisoning. Treatment should follow accepted modalities for a poisoned, altered, or seizing patient (6). Universal precautions should be taken to prevent secondary exposure of health-care workers. If TETS is suspected, regional poison control centers can provide information and guidance. A small study of rodents conducted in China suggested that intravenous pyridoxine and dimercaptosuccinic acid might be effective treatments (7). In China, charcoal hemoperfusion and hemodialysis are used to provide extracorporeal removal in patients poisoned with TETS (1,3) (Sun C, China NPCC, personal communication, 2002).

This is the first known case of TETS poisoning in the United States. The chemical's morbidity and lethality and the lack of a known antidote present a danger to human health in areas where TETS might be imported illegally, especially large urban areas with substantial immigrant populations. The appearance of a banned or illegal substance presents challenges to regulatory and enforcement agencies because of the increased risk for unintentional and intentional exposures. Poisoning caused by TETS exposure can be prevented with heightened public health education, increased awareness, and adequate enforcement by customs, border, and regulatory agencies.

Smallpox Vaccine Adverse Events Among Civilians — United States, March 4–10, 2003

During the civilian smallpox vaccination program, CDC, the Food and Drug Administration, and state health departments are conducting surveillance for vaccine-associated adverse events. In the first stage of the program, active surveillance is being conducted for potentially life-threatening, moderate-to-severe, and other serious adverse events and for vaccinia transmission to contacts of vaccinees (1) (Table). Nonserious events are reported through passive surveillance and are expected to be underreported. This report summarizes smallpox vaccine adverse events reported among civilians vaccinated as of March 7, 2003, and among contacts of vaccinees, received by CDC from the Vaccine Adverse Event Reporting System (VAERS) as of March 10. Potentially life-threatening and moderate-to-severe events are classified on the basis of evidence in support of the reported diagnoses. For probable cases, possible alternative etiologies are investigated, and supportive information is available. Events are classified as suspected if they have clinical features compatible with the diagnosis but either further investigation is required or additional investigation of the case did not provide supporting evidence for the diagnosis and did not identify an alternative diagnosis. CDC and state and local health departments also receive reports of other events that are associated temporally with smallpox vaccination. Reported adverse events are not necessarily associated with vaccination, and some or all of these events might be coincidental.

During January 24–March 7, smallpox vaccine was administered to 16,919 civilian health-care and public health workers in 50 jurisdictions. No potentially life-threatening adverse events of a type known previously to be caused by smallpox vaccination have been reported as of March 10.

During March 4–10, three moderate-to-severe adverse events were reported (Table). All were cases of inadvertent inoculation and were traced to contact with military personnel who received smallpox vaccine.

* Under investigation or completed as of March 10, 2003; numbers and classifications of adverse events , will be updated regularly in *MMWR* as more information becomes available.

¹₈ No cases reported.

[§] Three patients with inadvertent inoculation, non-ocular, and two patients who were contacts of military vaccinees.

¹¹ Events that result in hospitalization, permanent disability, life-threatening illness, or death; these events are associated temporally with smallpox vaccination but are not necessarily associated causally with vaccination.

** Include expected self-limited responses to smallpox vaccination (e.g., fatigue, headache, pruritis, local reaction at vaccination site, regional lymphadenopathy, lymphangitis, fever, myalgia and chills, and nausea); additional events are associated temporally with smallpox vaccination but are not necessarily ____ associated causally with vaccination.

¹¹ No cases of transmission from civilian vaccinees have been reported. Five cases of transmission from military personnel to civilian contacts have been reported.

On February 15, a man aged 23 years with no history of smallpox vaccination wrestled with a military recruit who had recently received smallpox vaccine and who had no covering in place over his inoculation site. On February 17, the patient noted a small pimple on his chest. A few days later, he noted a pustular lesion on his right shoulder. On March 3, the patient was assessed by local health authorities, who observed a 1.5 cm lesion on the patient's chest, with a welldefined scab and indurated center. A second 1.0 cm lesion was noted on the patient's face just below the nose and above his lip. The patient reported mild malaise but was otherwise well. Right axillary lymphadenopathy was noted on physical examination. On March 4, a swab specimen obtained from a pustular lesion tested positive for vaccinia DNA by real-time polymerase chain reaction (RT-PCR); confirmatory testing at CDC is pending.

On March 4, a woman aged 18 years with no history of smallpox vaccination reported to a local health department with a 0.5 cm pustular lesion on her right forearm, surrounded by a nearly 6.0 cm area of erythema. The lesion had developed during the previous 4 days after close physical

contact with her partner, a military vaccinee who was vaccinated on February 10. The vaccinee had maintained a small adhesive bandage over the lesion at all times, and the patient reported no sharing of towels or clothing; however, considerable oozing through the bandage was reported, which might have contaminated shared sheets and bedding. On March 6, a swab specimen from the pustular lesion tested positive for vaccinia DNA by RT-PCR.

On March 5, a woman aged 25 years with no history of smallpox vaccination was seen in an emergency department with three vesicular lesions on the proximal lateral aspect of her right arm. The patient was otherwise well. She reported close physical contact with a military vaccinee during February 14– 17, 2003. Swab specimens were obtained from the vesicular lesions for viral culture and direct flourescent antibody testing for vaccinia, herpes zoster, and herpes simplex virus; results are pending.

Four other serious adverse events were reported during March 4–10 (Table). None of these events was of a type known to be associated causally with vaccination.

On February 16, a woman aged 43 years was hospitalized 4 days after vaccination with chest pain and dyspnea. Cardiac catheterization revealed a pre-existing coronary artery anomaly. Angina considered to be related to this condition was diagnosed, and she was discharged the following day.

On February 26, a woman aged 53 years was hospitalized 8 days after vaccination with vomiting and diarrhea. Her symptoms improved after treatment with intravenous fluids and an antibiotic, and she was discharged the following day.

On February 28, a woman aged 57 years with a history of chronic obstructive pulmonary disease (COPD) was hospitalized 6 days after vaccination with an exacerbation of COPD, diarrhea, and dehydration. She was treated with intravenous fluids and was discharged the following day.

On February 28, a woman aged 45 years with a history of smallpox vaccination had sharp left shoulder pain and chest pain 2 days after vaccination. Her symptoms resolved after treatment with a nonsteroidal anti-inflammatory medication. Approximately 2 weeks before vaccination, she had onset of influenza-like illness (ILI) with fever, chill, myalgias, malaise, and cough, which were resolving at the time of vaccination after 1 week away from work. On March 3, she complained again of exertional chest pain and was hospitalized the following day with dyspnea and exertional chest pain that radiated to her neck. An echocardiogram on March 5 demonstrated a small pericardial effusion, left ventricular wall motion abnormality, and a mild decrease in left ventricular function. Cardiac catheterization found no evidence of coronary artery narrowing. Viral myocarditis judged to be associated with the antecedent ILI was diagnosed. On March 6, the patient was discharged after 2 days of hospitalization.

Among the 76 vaccinees with reported other nonserious adverse events during January 24–March 10 (Table), the most common signs and symptoms were rash (n = 20), fever (n = 18), pruritus (n = 17), and pain (n = 12). All of these commonly reported events are consistent with mild expected reactions following receipt of smallpox vaccine. Some vaccinees reported multiple signs and symptoms.

Surveillance for adverse events during the civilian smallpox vaccination program is ongoing; regular surveillance reports will be published in *MMWR*.

Satellite Broadcast on HIV Prevention

CDC and the Public Health Training Network will present a satellite broadcast and web cast, "Update on Rapid Testing for HIV," on Thursday, April 24, 2003, beginning at 1 p.m., EST. The 2-hour forum describes rapid tests for human immunodeficiency virus (HIV) including availability, administration, benefits and limitations, implementation considerations for counseling and testing, confirmatory testing for positive test results, quality assurance and training, and resources for updates on rapid testing. A panel of experts will address viewers' questions and comments, which can be sent by fax before, during, and after the program.

Additional information is available at http:// www.cdcnpin.org/broadcast and through CDC's Fax Information System, telephone 888-232-3299, by entering document number 130039 and a return fax number. Organizations are responsible for setting up their own viewing sites and are encouraged to register their sites as soon as possible so persons who want to view the broadcast can access information online. Directions for establishing and registering a viewing are available on the website. The broadcast also can be viewed live or later on computers with Internet and Real Player capability through a link at http://www.phppo.cdc.gov/phtn. Videotapes of the broadcast can be ordered while supplies last by telephone, 800-458-5231.

FDA Licensure of Diphtheria and Tetanus Toxoids and Acellular Pertussis Adsorbed, Hepatitis B (Recombinant), and Poliovirus Vaccine Combined, (PEDIARIX™) for Use in Infants

On December 13, 2002, the U.S. Food and Drug Administration (FDA) licensed a combined diphtheria and tetanus toxoids and acellular pertussis adsorbed (DTaP), hepatitis B (HepB) (recombinant) and inactivated poliovirus vaccine (IPV), DTaP-HepB-IPV (PEDIARIXTM, SmithKline Beecham Biologicals, Rixensart, Belgium) for use in infants ages 2, 4, and 6 months. All components in the combined vaccine are recommended for routine use by the Advisory Committee on Immunization Practices (ACIP), the Committee on Infectious Diseases of the American Academy of Pediatrics, and the American Academy of Family Physicians (*1,2*). Combination vaccines decrease the number of vaccine injections (*3*).

Each dose of DTaP-HepB-IPV contains the type and amount of diphtheria and tetanus toxoids and pertussis antigens and hepatitis B virus antigens as the DTaP and pediatric formulation of hepatitis B vaccine from the same manufacturer (INFANRIX[®] and ENGERIX-B[®], respectively). The poliovirus component of DTaP-HepB-IPV contains the same strains and quantity of inactivated poliovirus Types 1, 2, and 3 as IPV from a different manufacturer (IPOL[®], Aventis Pasteur, South Africa) (4).

MMWR

The immunologic responses following 3 doses of DTaP-HepB-IPV were generally similar to those following 3 doses of separately administered INFANRIX[®], ENGERIX-B[®], and oral poliovirus vaccine (5). Immunogenicity data from simultaneous administration of DTaP-HepB-IPV, with both *Haemophilus influenzae* type b (Hib) conjugate vaccine and pneumococcal conjugate vaccine (PCV), are unavailable (4).

Except for fever, the rates of most solicited local and systemic adverse events following DTaP-HepB-IPV were comparable to rates observed following separately administered U.S.-licensed vaccines. In comparative studies, administration of DTaP-HepB-IPV and Hib vaccine was associated with higher rates of fever relative to separately administered vaccines (5,6). In an ongoing study, infants who received the first dose of DTaP-HepB-IPV with Hib vaccine and PCV had higher rates of fever compared with infants who received separately administered vaccines (4).

ACIP Approval of DTaP-HepB-IPV for the Vaccine for Children Program

ACIP has approved the use of PEDIARIXTM for the Vaccine for Children program and recommends that, in addition to FDA-approved uses, 3 doses of PEDIARIXTM can be administered to an infant who is born to a woman who is hepatitis B surface antigen (HBsAg)-positive or whose HBsAg status is unknown. ACIP also approved a minimum interval of 4 weeks between the first and second doses when used in an accelerated vaccination schedule; the third dose should not be given before age 24 weeks.

Indications and Usage

Primary series

204

- DTaP-HepB-IPV is approved for the primary series at ages 2, 4, and 6 months. The vaccine should not be administered to any infant aged <6 weeks or any person aged ≥7 years. The recommended interval between doses is 6–8 weeks (preferably 8 weeks) (4).
- 2. DTaP-HepB-IPV can be used to complete the primary series in infants and children who have received INFANRIX[®] (DTaP) and are scheduled to receive the other components of the combination. Data are limited on the safety and immunogenicity of interchanging currently used DTaP vaccines from different manufacturers (7). ACIP recommends that, whenever feasible, the same brand of DTaP should be used for the primary series but that vaccination should not be deferred because the type of DTaP previously administered is unavailable or unknown (7).

- 3. All infants should receive a single antigen HepB vaccine soon after birth and before hospital discharge; the first dose can be given by age 2 months if the infant's mother is HbsAg-negative (1). For optimal prevention of perinatal infection, infants born to women who are HBsAg-positive must receive their first dose of single antigen HepB vaccine and hepatitis B immune globulin (HBIG) within 12 hours of birth and ≥ 3 doses of HepB vaccine by 6 months of age. Women of unknown HBsAg status who give birth should be tested for HBsAg immediately and their infants administered single antigen HepB vaccine within 12 hours of birth; these infants also should receive HBIG if the woman is found to be HBsAg-positive. Except for doses administered at age <6 weeks of age, DTaP-HepB-IPV can be used in a HepB vaccine series for any infant. However, infants born to HBsAg-positive women should begin DTaP-HepB-IPV beginning by age 6-8 weeks after receiving single antigen vaccine at birth. Use of DTaP-HepB-IPV after single antigen HepB vaccine is administered at birth will result in a 4-dose HepB vaccine series (1); this is considered acceptable by ACIP (3).
- DTaP-HepB-IPV and HepB vaccine from a different manufacturer are interchangeable for HepB vaccination (3). DTaP-HepB-IPV and IPV from a different manufacturer are interchangeable for poliovirus vaccination (4).
- 5. DTaP-HepB-IPV combination can be administered with Hib and PCV vaccines at separate injection sites (7).

Boosters

1. The DTaP-HepB-IPV combination is not approved for the fourth dose of IPV or the fourth and fifth dose of DTaP (4).

Errata: Vol. 52, No. RR-1

In the *MMWR Recommendations and Reports*, "Prevention and Control of Infections with Hepatitis Viruses in Correctional Settings," published on January 24, 2003, an error occurred on page 4 in the second sentence of the paragraph under Occupational Exposures. The sentence should read, "Occupational transmission of HBV infection among hospital-based workers has been linked to percutaneous and mucous membrane exposures, and HCV infection has been primarily associated with percutaneous exposure."

On page 12, in Box 6, the fourth item under Type of Exposure should read, "Household (e.g., cell or dormitory) contact — to person with chronic HBV infection."

On page 2, errors occurred in Table 1, and on page 20, errors occurred in Table 5. The correct tables follow.

TABLE 1. Estimated chronic infections with hepatitis viruses among inmates and releasees — United States, 1997

* Persons who have previously been infected with HBV are immune to reinfection and do not require postexposure prophylaxis.

[†] Hepatitis B surface antigen.

§ Inmates should be considered persons at probable high risk.

[¶] Hepatitis B immune globulin; dose is 0.06 mL/kg body weight intramuscularly.

** Hepatitis B vaccine.

⁺⁺ A responder is a person with adequate levels of serum antibody to HBsAg (i.e., anti-HBs ≥10 mlU/mL).

§ A nonresponder is a person with inadequate response to vaccination (i.e., anti-HBs <10 mlU/mL).

The option of administering one dose of HBIG and reinitiating the vaccine series is preferred for nonresponders who have not completed a second 3-

dose vaccine series. For persons who previously completed a second vaccine series but failed to respond, 2 doses of HBIG are preferred.

⁺⁺⁺ For persons with ongoing exposure, such as health-care workers, recheck anti-HBs level in 1 month.

U: Unavailable. -: No reported cases.

Or Unavailable. --No reported cases.
* Mortality data in this table are voluntarily reported from 122 cities in the United States, most of which have populations of ≥100,000. A death is reported by the place of its occurrence and by the week that the death certificate was filed. Fetal deaths are not included.
† Pneumonia and influenza.
§ Because of changes in reporting methods in this Pennsylvania city, these numbers are partial counts for the current week. Complete counts will be available in 4 to 6 weeks.
† Total includes unknown ages.

All MMWR references are available on the Internet at http://www.cdc.gov/mmwr. Use the search function to find specific articles.

Use of trade names and commercial sources is for identification only and does not imply endorsement by the U.S. Department of Health and Human Services.

References to non-CDC sites on the Internet are provided as a service to *MMWR* readers and do not constitute or imply endorsement of these organizations or their programs by CDC or the U.S. Department of Health and Human Services. CDC is not responsible for the content of these sites. URL addresses listed in *MMWR* were current as of the date of publication.

The Morbidity and Mortality Weekly Report (MMWR) Series is prepared by the Centers for Disease Control and Prevention (CDC) and is available free of charge in electronic format and on a paid subscription basis for paper copy. To receive an electronic copy each week, send an e-mail message to *listserv@listserv.cdc.gov*. The body content should read *SUBscribe mmwr-toc*. Electronic copy also is available from CDC's World-Wide Web server at http://www.cdc.gov/mmwr or from CDC's file transfer protocol server at ftp://ftp.cdc.gov/pub/publications/ mmwr. To subscribe for paper copy, contact Superintendent of Documents, U.S. Government Printing Office, Washington, DC 20402; telephone 202-512-1800.

Data in the weekly *MMWR* are provisional, based on weekly reports to CDC by state health departments. The reporting week concludes at close of business on Friday; compiled data on a national basis are officially released to the public on the following Friday. Address inquiries about the *MMWR* Series, including material to be considered for publication, to Editor, *MMWR* Series, Mailstop C-08, CDC, 1600 Clifton Rd., N.E., Atlanta, GA 30333; telephone 888-232-3228.

All material in the MMWR Series is in the public domain and may be used and reprinted without permission; citation as to source, however, is appreciated.
