## Tobacco Use Among Adults — United States, 2005

Four of the Healthy People 2010 objectives\* regarding tobacco use are to reduce the prevalence of cigarette smoking to 12.0%, cigar smoking to 1.2%, use of smokeless tobacco to 0.4%, and to increase cessation attempts among adult smokers to 75.0% (1). To assess progress toward achieving these four objectives, CDC analyzed self-reported data from the 2005 National Health Interview Survey (NHIS). This report summarizes the results of these analyses, which indicated lagging progress on all four objectives. In 2005, approximately 20.9% of U.S. adults were current cigarette smokers, the same percentage as in 2004 (2), suggesting that the 8-year decline in smoking prevalence among adults in the United States might be stalling. In addition, the findings indicated that, in 2005, an estimated 2.2% of U.S. adults were current cigar smokers, 2.3% used smokeless tobacco, and 42.5% of current cigarette smokers had stopped smoking for at least 1 day in the preceding 12 months because they were trying to quit (Figure). To meet the Healthy People objectives for 2010, full implementation of effective, comprehensive tobacco-control programs that address both initiation and cessation of tobacco use is needed in all states and U.S. territories.

The 2005 NHIS adult core questionnaire, which contained questions on cigarette smoking and cessation attempts, was administered by in-person interview to a nationally representative sample of 31,428 persons from the noninstitutionalized U.S. civilian population aged  $\geq$ 18 years. The same respondents were administered a supplemental questionnaire on cancer that contained questions regarding cigar smoking and use of smokeless tobacco (i.e., chewing tobacco and snuff). The response rate for both the adult core sample and supplemental questionnaire was 69.0%. Data were adjusted for nonresponse and weighted to provide national estimates of cigarette and cigar smoking, use of smokeless tobacco, and cessation attempts. Confidence intervals (CIs) were calculated using statistical software to account for the survey's multistage probability sample design.

To measure cigarette smoking, respondents were asked, "Have you smoked at least 100 cigarettes in your entire life?" and "Do you now smoke cigarettes every day, some days, or not at all?" Current cigarette smokers had smoked at least 100 cigarettes during their lifetimes and reported smoking every day or some days. Current cigar smokers had smoked at least 50 cigars during their lifetimes and reported smoking cigars every day or some days. Current users of smokeless tobacco had used chewing tobacco or snuff at least 20 times during their lifetimes and reported using chewing tobacco or snuff every day or some days. Among current cigarette smokers, making at least one cessation attempt in the preceding year was defined as a "yes" response to the question, "During the past 12 months, have you stopped smoking for more than one day because you were trying to quit smoking?"

In 2005, an estimated 20.9% (45.1 million) of U.S. adults were current cigarette smokers; of these, 80.8% (36.5 million) smoked every day, and 19.2% (8.7 million) smoked some days. The prevalence of current cigarette smoking varied substantially across population subgroups (Table). Current smoking was higher among men (23.9%) than women (18.1%). Among

racial/ethnic groups, American Indians and Alaska Natives had the highest prevalence (32.0%), followed by non-Hispanic whites (21.9%), and non-Hispanic blacks (21.5%). Asians (13.3%) and Hispanics (16.2%) had the lowest rates.

By education level, smoking prevalence was highest among adults who had earned a General Educational Development (GED) diploma (43.2%) and those with 9–11 years of education (32.6%); prevalence generally decreased with increasing education. Adults aged 18–24 years (24.4%) and 25–44 years (24.1%) had the highest prevalences. The prevalence of current smoking was higher among adults living below the poverty level (29.9%) than among those at or above the poverty level (20.6%) (Table).

Certain populations had already surpassed the 2010 target of 12% for current cigarette smoking prevalence. These included Hispanic (11.1%) and Asian (6.1%) women, women with undergraduate (9.6%) or graduate (7.4%) degrees, men with undergraduate (11.9%) or graduate (6.9%) degrees, men aged  $\geq$ 65 years (8.9%), and women aged  $\geq$ 65 years (8.3%) (Table).

Among current cigarette smokers, an estimated 42.5% (95% CI =  $\pm 1.7$ ; 19.2 million) had stopped smoking for at least 1 day during the preceding 12 months because they were trying to quit. Among the estimated 42.5% (91.8 million) of persons who had smoked at least 100 cigarettes during their lifetimes, 50.8% (46.5 million) did not smoke currently. In 2005, prevalence of current cigar smoking was 2.2% (CI =  $\pm 0.2$ ) and current smokeless tobacco use was 2.3% (CI =  $\pm 0.3$ ). Prevalence of cigar smoking and use of smokeless tobacco were higher among men (4.3% and 4.5%, respectively) than women (0.3% and 0.2%).

**Reported by:** *P Mariolis, PhD, VJ Rock, MPH, K Asman, MSPH, R Merritt, MA, A Malarcher, PhD, C Husten, MD, T Pechacek, PhD, Office on Smoking and Health, National Center for Chronic Disease Prevention and Health Promotion, CDC.* 

**Editorial Note:** The findings in this report indicate that the prevalence of cigarette smoking among U.S. adults did not change from 2004 to 2005. The adult prevalence might represent a stall in the decline in current cigarette smoking during the preceding 8 years and mirrors a lack of decline in smoking among adolescents since 2002 (*3*). Influencing factors might include smaller annual increases in the retail price of cigarettes (*4*) and a 26.5% reduction in funding for comprehensive state programs in tobacco control and prevention from 2002 to 2006 (*5*). Additionally, tobacco-industry advertising and promotional expenditures, primarily focused on price-discounting strategies, more than doubled from \$6.7 billion in 1998 to \$15.1 billion in 2003 (*6*).

The rate of decrease in cigarette smoking among adults is not sufficient to meet the 2010 objective of 12%, and the

rates of improvements are also not sufficient to meet the objectives for cigar smoking, use of smokeless tobacco, and attempts at smoking cessation. In addition, prevalence remains high among certain segments of the population. For example, in 2005, the prevalence was 43.2% among persons with a GED diploma and 32.6% among persons with education levels of 9–11 years.

Effective interventions have been identified for decreasing initiation and increasing cessation, but they have not been implemented adequately (7,8). Recommended interventions include increases in the unit price for tobacco, mass media campaigns in combination with other interventions, and community mobilization campaigns to restrict access of minors to tobacco products in conjunction with enactment and enforcement of stronger retail sales laws and retailer education (8). Additional recommended interventions include reducing outof-pocket costs to smokers for effective cessation therapies, multicomponent interventions (e.g., patient education, individual or group counseling, or nicotine replacement therapies) that include telephone quitlines, and health-care system changes (e.g., healthcare provider reminder systems) (8).

The findings in this report are subject to at least three limitations. First, estimates for cigarette smoking are based on self report and are not validated by biochemical tests. However, self-reported data on current smoking status have been determined to have high validity when compared with measured serum cotinine levels (9). Second, the NHIS questionnaire is administered in English and Spanish only, which might result in imprecise estimates for racial/ethnic populations unable to respond to the survey because of language barriers. Third, the small NHIS samples for certain populations (e.g., American Indians/Alaska Natives) result in singleyear estimates with large confidence intervals.

The lack of progress in reducing tobacco use and increasing cessation attempts among U.S. adults underscores the need for increasing measures to establish sustained, comprehensive, evidence-based tobacco-control programs that address both initiation and cessation. Full implementation of these programs at CDC-recommended lev-

els of funding would accelerate progress toward meeting the 2010 objectives and decreasing the health burden and economic impact of tobacco-related diseases (7,8).

## State-Specific Prevalence of Current Cigarette Smoking Among Adults and Secondhand Smoke Rules and Policies in Homes and Workplaces — United States, 2005

Smoking causes premature death and disease in children and adults who do not smoke but are exposed to secondhand smoke (SHS) (1). To assess the state-specific prevalence of current smoking among adults in the United States and the proportions of adults who report having smoke-free home rules\* and smoke-free policies<sup>†</sup> in their workplace, CDC analyzed data from the 2005 Behavioral Risk Factor Surveillance System (BRFSS) (2). This report summarizes the results of that analysis, which indicated a threefold difference (from lowest to highest) in self-reported cigarette smoking prevalence in 50 states, the District of Columbia (DC), Puerto Rico (PR), and the U.S. Virgin Islands (USVI) (range: 8.3%-28.7%). Wide variations also were observed in USVI and the 14 states that assessed prevalence of smoke-free home rules (from 63.6% [Kentucky] to 82.9% [Arizona]) and smoke-free workplace policies (from 54.8% [Nevada] to 85.8% [West Virginia]). Evidence-based, comprehensive tobacco prevention and control programs that focus on decreasing smoking initiation, increasing smoking cessation, and establishing smoke-free workplaces, homes, and other venues should be continued and expanded to reduce smoking prevalence, exposure of nonsmokers to SHS, and smoking-related morbidity and mortality.

BRFSS is a state-based, random-digit-dialed telephone health survey of the noninstitutionalized, U.S. civilian population aged  $\geq$ 18 years. The 2005 BRFSS was conducted in 50 states, DC, PR, and USVI. The questions to assess SHS rules and policies were offered as an optional module and were used in 14 states and USVI. Estimates were weighted by age and sex distribution for each state/area population, and 95% confidence intervals were calculated. Because BRFSS data are statespecific, median prevalences rather than national averages are reported. The territories (PR and USVI) were excluded in the calculation of median prevalence. The median response rate among all states and DC was 51.1% (range: 34.6%–67.4%) (2).

<sup>\*</sup> Home smoke-free rules are private household rules that are adopted voluntarily by household members. They can include comprehensive rules that make homes smoke-free in all areas at all times and less comprehensive rules that restrict smoking to certain places or times (*1*).

<sup>&</sup>lt;sup>†</sup>Workplace smoke-free policies regarding smoking in public areas and work areas are established either by legislation (at the local or state level) or through smoke-free policies adopted voluntarily by employers.

Respondents were asked, "Have you smoked at least 100 cigarettes in your entire life?" and "Do you now smoke cigarettes every day, some days, or not at all?" Current smokers were defined as those who reported having smoked at least 100 cigarettes during their lifetimes and who currently smoke every day or some days. To assess smoke-free home rules, respondents were asked, "Which statement best describes the rules about smoking inside your home?" The response options were 1) "Smoking is not allowed anywhere inside your home," 2) "Smoking is allowed in some places or at some times," 3) "Smoking is allowed anywhere inside your home," and 4) "There are no rules about smoking inside your home." To assess smoke-free workplace policies, persons who reported that they were employed and worked indoors most of the time were asked, "Which of the following best describes your place of work's official policy for indoor public or common areas, such as lobbies, rest rooms, and lunch rooms?" and "Which of the following best describes your place of work's official smoking policy for work areas?" Response options for the first question were 1) "Not allowed in any public areas," 2) "Allowed in some public areas," 3) "Allowed in all public areas," and 4) "No official policy." Response options for the second question were 1) "Not allowed in any work areas," 2) "Allowed in some work areas," 3) "Allowed in all work areas," and 4) "No official policy."

## **Current Cigarette Smoking Prevalence**

During 2005, the median adult smoking prevalence among all 50 states and DC was 20.6% (range: 11.5%–28.7%) (Table 1). Smoking prevalence was highest in Kentucky (28.7%), Indiana (27.3%), and Tennessee (26.8%) and was lowest in Utah (11.5%), California (15.2%), and Connecticut (16.5%). Smoking prevalence was 8.3% in USVI and 13.1% in PR. In the majority of states, men had a higher smoking prevalence (median: 22.1% [range: 13.7%–30.6%]) than women (median: 19.2% [range: 9.3%–26.9%]).

## Smoke-Free Policies in Homes and Workplaces

In the 14 states that asked about smoking restrictions in homes and workplaces, the median percentage of persons who reported that smoking is not allowed anywhere inside their homes (i.e., complete smoke-free home rule) was 73.7%, and the median percentage of persons who worked mostly indoors and reported that smoking is not allowed in any indoor public areas or work areas within their workplaces (i.e., complete smoke-free workplace policy) was 73.4% (Table 2). In USVI, 82.4% of persons reported complete smoke-free home rules, and 66.6% reported complete smoke-free workplace policies. TABLE 1. Prevalence of current cigarette smoking among adults,\* by state/area and sex — Behavioral Risk Factor Surveillance System, 50 states, District of Columbia, Puerto Rico, and the U.S. Virgin Islands, 2005

TABLE 2. Proportion of adults\* who reported complete smoking restrictions inside their homes and in public or work areas in their workplaces, by state/area — Behavioral Risk Factor Surveillance System, 14 states and the U.S. Virgin Islands, 2005

\* Persons aged  $\geq$ 18 years.

<sup>†</sup> Smoking is not allowed anywhere inside the home.

§ Among persons who worked indoors most of the time, percentage who reported that smoking is not allowed in any public areas in their workplaces.

<sup>¶</sup> Among persons who worked indoors most of the time, percentage who reported that smoking is not allowed in any work areas in their workplaces.

\*\* Among persons who worked indoors most of the time, percentage who reported that smoking is not allowed in any public or work areas in their workplaces.

<sup>††</sup> Confidence interval.

§§ Calculation of median values excluded territories (i.e., U.S. Virgin Islands).

In all 14 states and USVI, respondents reported higher percentages of complete smoke-free policies in work areas (median: 85.5%<sup>§</sup> [range: 76.2%–92.2%]) than in public areas of their workplaces (median: 79.0% [range: 60.1%– 88.1%]). The states with the highest percentages of smoke-free home rules were Arizona (82.9%) and Nevada (79.0%); the states with the lowest percentages were Kentucky (63.6%) and West Virginia (65.4%). The states with the highest percentages of smoke-free workplace policies were West Virginia (85.8%) and Iowa (77.7%); Nevada (54.8%) and Arkansas (61.3%) had the lowest percentages.

**Reported by:** E Maurice, MS, S Thorne, MPH, U Ajani, MBBS, A Malarcher PhD, R Merritt, MA, C Husten, MD, Office on Smoking and Health, National Center for Chronic Disease Prevention and Health Promotion, Coordinating Center for Health Promotion, CDC.

**Editorial Note:** *Healthy People 2010* objectives call for reducing adult cigarette smoking prevalence to 12% (objective 27-1), reducing the proportion of nonsmokers exposed to SHS to 45% (objective 27-10), and increasing the proportion of work-places and workers that are covered by smoke-free workplace policies to 100% (objective 27-12) (3). In 2005, Utah and USVI; women in Utah, California, and USVI; and men in USVI continued to meet the *Healthy People 2010* objective

for reducing adult smoking prevalence, as they did in 2004. Women in PR achieved the goal for the first time in 2005. Men in Utah met the goal in 2004 (11.7%) but not in 2005 (13.7%) (4). The present rate of decline in current smoking rates is not fast enough for most states to achieve the *Healthy People 2010* objective of 12% (objective 27-1).

Because the majority of SHS exposure among nonsmokers occurs in workplaces and homes, the only interventions that effectively protect nonsmokers from SHS exposure are legislation, policies, and rules that make workplaces and homes completely smoke-free (1). SHS exposure has decreased substantially during the past 20 years, in part because many employers and communities and certain states have implemented smoke-free policies and laws. As of March 1, 2006, six states (Delaware, Massachusetts, New Jersey, New York, Rhode Island, and Washington) had implemented laws (effective on or before June 1, 2006) that make private workplaces, restaurants, and bars smoke-free (5). In addition, several other states have implemented laws that make one or two of these three settings smoke-free. However, the findings in this report indicate that a substantial proportion of adults remain at risk for SHS exposure in their homes and workplaces because of lack of smoke-free rules and policies. Among the 14 states that used the optional SHS module, only Oklahoma has had statewide smoke-free laws for private

<sup>§</sup> Calculation of median values excluded USVI.

workplaces since September 2003, but restaurants in Oklahoma were not included until March 1, 2006.

The patterns of current smoking among U.S. adults might be beginning to mirror the current smoking patterns among middle and high school students, which have not changed substantially from 2002 to 2005; smoking prevalence rates in this student population have stabilized in the past few years (6). The lack of change in cigarette smoking might be attributed to the substantial increase in marketing expenditures by tobacco companies since 1998 and decreases in state funding for comprehensive tobacco-control programs since 2002 (7,8). In 2003, tobacco companies spent approximately \$15.1 billion on advertising and promotion, which more than doubled these expenditures from 1998 (7). The Federal Trade Commission reported that price discounts paid to retailers or wholesalers to reduce the price of cigarettes to consumers accounted for \$10.8 billion (71.4% of total advertising and promotional spending by tobacco companies in 2003) (7). In contrast, in the state fiscal year 2006, Colorado, Delaware, Maine, and Mississippi were the only states that funded their tobaccocontrol programs at the minimum levels recommended by CDC (8,9).

The findings in this report are subject to at least four limitations. First, BRFSS does not sample persons in households without landline telephones, a population that might be more likely to smoke (2). In 2005, an estimated 94.2% of the U.S. population had telephones; however, noncoverage ranged from 2.1% of households in Connecticut to 10.0% of households in Arkansas and 23.8% in PR (2). Second, several states did not collect data for all 12 months of the year because of the severe hurricane season. Data from Mississippi and Louisiana only include information collected during January-August. PR did not collect data in March, and USVI did not collect data in July, October, and November. Third, estimates for cigarette smoking are based on self-report and are not validated by biochemical tests. However, self-reported data on current smoking status have been shown to have high validity (2). Finally, the median response rate was 51.1% (range: 34.6%-67.4%); however, the reliability and validity of BRFSS measures have been demonstrated (2).

In the recently released report, the Surgeon General concluded that SHS causes premature death and disease in children and in adults who do not smoke (1). Children exposed to SHS are at increased risk for SIDS, acute respiratory infections, ear problems, and more severe asthma (1). The home is the place where children are most exposed to SHS, and children remain more heavily exposed to SHS than adults (1). Exposure of adults to SHS has immediate adverse effects on the cardiovascular system and causes coronary heart disease and lung cancer (1). The Surgeon General's report concludes that no risk-free level of SHS exposure exists (1). The report also concludes that eliminating smoking in indoor spaces fully protects nonsmokers from SHS exposure, whereas separating smokers from nonsmokers, cleaning the air, and ventilating buildings cannot eliminate this exposure (1). Laws and regulations that create smoke-free worksites and public places should be implemented to protect the health of the public. Everyone is encouraged to make their homes smoke-free to protect themselves and their families from exposure to SHS.

Consumer education materials describing what the public, parents, and employers can do to make their environments smoke-free are available online at http://www.surgeongeneral.gov/ library/secondhandsmoke/secondhandsmoke.pdf. Implementing smoke-free rules and policies in conjunction with other elements of a comprehensive tobacco-control program, such as increasing tobacco excise taxes, having sustained countermarketing campaigns, expanding access to quitline services, and increasing insurance coverage for tobacco-use treatment (10), have been shown to increase cessation, decrease consumption, and decrease SHS exposure. Implementing comprehensive state tobacco-control programs that are funded at the minimum levels recommended by CDC (9) would accelerate progress in reducing tobacco use and SHS exposure.

## Brief Report

## Update: Mumps Activity — United States, January 1–October 7, 2006

During January 1–October 7, 2006, a total of 45 states\* and the District of Columbia reported 5,783 confirmed or probable mumps cases to CDC (Figure). This includes 2,597 cases previously reported by 11 states during January 1–April 29, 2006 (1). This report summarizes the epidemiology of mumps cases in the United States during 2006. With low levels of reported mumps continuing, health-care workers should remain alert to suspected mumps, conduct appropriate laboratory testing, and use every opportunity to ensure adequate immunity, particularly among populations at high risk for mumps.

Cases of mumps are reportable through the National Notifiable Diseases Surveillance System (NNDSS). Reports are transmitted electronically via NNDSS to CDC each week and include individual case information such as age, sex, date of symptom onset, vaccination status, and complications of illness. Mumps cases included in this report are those with onset from January 1 (week 1) through October 7, 2006 (week 40).

The clinical case definition of mumps is an illness with acute onset of unilateral or bilateral tender, self-limited, swelling of the parotid or other salivary gland, lasting 2 or more days, and without other apparent cause. A confirmed case of mumps is one that is laboratory confirmed or meets the clinical case definition and is linked epidemiologically to a confirmed or probable case. A probable case meets the clinical case definition but is neither laboratory confirmed nor linked to another confirmed or probable mumps case (2).

Of the 5,783 cases, 3,113 (54%) were confirmed, and 2,612 (45%) were probable; for 58 cases (1%), classification was unknown. Six states reported 84% of the cases: Iowa (1,968), Kansas (904), Wisconsin (750), Illinois (591), Nebraska (357), and South Dakota (288).

For 5,747 (99%) of the 5,783 mumps cases with patient age available, the median age was 22 years (range: 1 month–96 years). Among the 5,739 (99%) patients for whom sex was known, 3,644 (63%) were female. As reported previously (1), the highest age-specific rate continues to be among persons aged 18–24 years, many of whom were college students.

Data regarding vaccination status are incomplete. In Iowa, one of the states with the most complete data, preliminary vaccination data have been reported through September 30. Among 1,798 patients with completed follow-up reports, 123

FIGURE. Number of mumps cases,\* by month of onset -

\* Provisional number of cases (N = 5,783) as reported to the National Notifiable Diseases Surveillance System.

(7%) were unvaccinated; 245 (14%) had received 1 dose of measles, mumps, and rubella (MMR) vaccine, and 884 (49%) had received  $\geq$ 2 doses of MMR vaccine. The vaccination status of 546 (30%) patients, the majority of whom were adults, was unknown (*3*).

Among the 5,783 cases for which weeks of onset are known, cases peaked during April 16-29, the onset period for 1,498 (26%) cases (Figure). The number of reported cases decreased during May-September, when most students were not attending college. However, since students began returning to school in August, mumps clusters have been reported from three college or university campuses in Illinois (84 cases), Kansas (22 cases), and Virginia (12 cases). Most of these cases (96%) were reported in persons who had received 2 doses of MMR vaccine. Because 2 doses of mumps-containing vaccine are not 100% effective, in a setting with high vaccination coverage such as the United States, most mumps cases likely will occur in persons who have received the 2 doses. Multiple other factors might have contributed to the spread of the mumps outbreak (e.g., the close-contact environment of college dormitories or varying college admission requirements for MMR vaccination) (1).

Health-care providers should continue to remain alert for suspected mumps cases, conduct appropriate diagnostic testing, and report these cases to local or state health departments. At the initial visit, recommended specimens for laboratory testing include serum to test for mumps immunoglobulin M (IgM) antibodies and a swab from the parotid duct or other affected salivary gland ducts for viral isolation, reverse transcriptase–polymerase chain reaction testing, or both. Parotid duct swab is the preferred viral sample for mumps; urine samples are no longer recommended. The first (acute) serum

<sup>\*</sup> Five states (Connecticut, Delaware, Maine, Montana, and Vermont) did not report any cases to CDC.

specimen should be collected within 5 days of illness onset. If the IgM antibody titer is negative, a second (convalescent) serum specimen for IgM antibodies is recommended 2-3 weeks after onset of signs (e.g., parotitis) or symptoms; a delayed IgM response has been observed in patients with confirmed cases of mumps, especially in vaccinated persons. The paired serum specimens also can be used to detect a significant rise (as defined by the testing kit instructions) in immunoglobulin G (IgG seroconversion) if measured by enzyme-linked immunosorbent assay or a fourfold rise in titer if measured using plaque-reduction neutralization assays or similar quantitative assay. Negative laboratory tests, especially in vaccinated persons, should not be used to rule out a mumps diagnosis, because these tests are not sensitive enough to detect infection in all persons with clinical illness. In the absence of another diagnosis, cases meeting the clinical case definition should be reported as mumps cases.

In response to this nationwide mumps outbreak, ACIP recommendations for prevention and control of mumps were updated (4). Evidence of immunity through documentation of vaccination is now defined as 1 dose of live mumps vaccine for preschool-aged children and adults not at high risk for exposure and infection and 2 doses of live mumps vaccine for school-aged children (i.e., grades kindergarten-12) and adults at high risk for exposure and infection (i.e., health-care workers, international travelers, and students at post-high-school education institutions). Additional recommendations for outbreak control include administering a second dose of MMR for preschool children and adults not at high risk for exposure and infection if these persons are part of a group that is experiencing an outbreak (4). To ensure high levels of immunity, especially among groups at high risk for exposure and infection, every opportunity should be used to provide the first or second dose of MMR vaccine to those without adequate evidence of immunity (e.g., documentation of vaccination). Private health-care providers, clinics, health departments, health-care institutions, schools, universities, and colleges should consider offering MMR vaccine through such settings as routine preventive health services and special immunization clinics, including providing MMR in conjunction with influenza vaccine.

### Notice to Readers

## National Epilepsy Awareness Month — November 2006

November is National Epilepsy Awareness Month. In 2006, epilepsy affects approximately 3 million persons in the United States and is characterized by recurrent, unprovoked seizures. Delayed recognition of seizures and inadequate treatment increase the risk for subsequent seizures, brain damage, disability, decreased health-related quality of life, and death from injuries incurred during a seizure.

Epilepsy most often affects young children and older adults, although persons can have epilepsy at any age. The effects of epilepsy on children can be especially problematic as they transition into adult activities (e.g., driving and working). The number of cases among older adults is increasing as the U.S. population ages.

The Epilepsy Foundation, in partnership with CDC, is continuing its national programs to improve the health care and community support available to persons affected by epilepsy through public education and community awareness programs. The theme for this year's foundation campaign, which begins in November and will extend throughout the year, is "Not another moment lost to seizures." The campaign includes initiatives targeting outreach and education to young persons, seniors, blacks, and Hispanics. The foundation also is developing a first responders curriculum to train emergency response personnel. In addition, the foundation has established partnerships with other national and local organizations to provide public education and community awareness programs. These organizations include the National Association of School Nurses, American Association of Retired Persons, Community Health Workers/Promotores National Network, National Council of La Raza, National Center for Farmworker Health, and East Coast Community Health Centers Association.

Information regarding epilepsy and the campaign is available from the Epilepsy Foundation by telephone (800-332-1000) or at http://www.epilepsyfoundation.org. Information in Spanish is available at http://www.fundacionparalaepilepsia.org or by telephone (866-748-8008).

## Self-Study Course: Principles of Epidemiology in Public Health Practice, Third Edition

The introductory self-study course, Principles of Epidemiology in Public Health Practice, Third Edition, is now available online. The course is designed for public health professionals at the state and local level who have, or expect to have, responsibility for outbreak investigations or public health surveillance. The course provides an introduction to applied epidemiology and biostatistics; it consists of six lessons: Introduction to Epidemiology, Summarizing Data, Measures of Risk, Displaying Public Health Data, Public Health Surveillance, and Investigating an Outbreak. Continuing education credits are offered to physicians, nurses, veterinarians, pharmacists, certified public health educators, and other professionals.

The self-study course (SS1000) is available at no charge at http://www2a.cdc.gov/phtnonline. A printed copy of the course can be ordered from the Public Health Foundation at http://bookstore.phf.org, or at telephone, 877-252-1200 (United States) or 301-645-7773 (international).

# **QuickStats**

#### FROM THE NATIONAL CENTER FOR HEALTH STATISTICS

## Percentage of Infants\* Born During 1990–1993 and 1997–2000 Who Were Ever Breastfed, by Race/Ethnicity of Mother — United States

\* Excludes twins and higher-order multiple births.

The percentage of infants ever breastfed increased from 55% among those born during 1990–1993 to 67% among those born during 1997–2000, bringing the levels of breastfeeding initiation closer to the *Healthy People 2010* objective of 75% among mothers in all racial/ethnic groups. Substantial progress toward meeting this goal has been observed among Hispanic (75%) and non-Hispanic white (69%) mothers. In addition, breastfeeding initiation nearly doubled among non-Hispanic black mothers, from 25% of infants born during 1990–1993 to 47% of infants born during 1997–2000.

Cum: Cumulative year-to-date counts. -: No reported cases. N: Not notifiable.

Incidence data for reporting year 2006 are provisional, whereas data for 2001, 2002, 2003, 2004, and 2005 are finalized.

t Calculated by summing the incidence counts for the current week, the two weeks preceding the current week, and the two weeks following the current week, for a total of 5 preceding years. Additional information is available at http://www.cdc.gov/epo/dphsi/phs/files/5yearweeklyaverage.pdf.

Ş Not notifiable in all states.

Includes both neuroinvasive and non-neuroinvasive. Updated weekly from reports to the Division of Vector-Borne Infectious Diseases, National Center for Zoonotic, Vector-Borne, and Enteric Diseases (proposed) (ArboNET Surveillance).
 \*\* Data for *H. influenzae* (all ages, all serotypes) are available in Table II.

\*\*

Updated monthly from reports to the Division of HIV/AIDS Prevention, National Center for HIV/AIDS, Viral Hepatitis, STD, and TB Prevention (proposed). Implementation of HIV reporting influences the number of cases reported. Pediatric HIV data will not be updated monthly for the remainder of this year due to upgrading of the national HIV/AIDS surveillance data management system. Data for HIV/AIDS are available in Table IV quarterly. **††** 

§§ Updated weekly from reports to the Influenza Division, National Center for Immunization and Respiratory Diseases (proposed).

¶¶ Cumulative totals for 2005 and 2006 do not include reports from states where influenza-associated pediatric mortality is not a notifiable condition.

\*\*\* No measles cases were reported for the current week.

ttt Data for meningococcal disease (all serogroups and unknown serogroups) are available in Table II.

U: Unavailable.

 $\frac{1}{2}$ : Unavailable. -:No reported cases. \* Mortality data in this table are voluntarily reported from 122 cities in the United States, most of which have populations of  $\geq$ 100,000. A death is reported by the place of its occurrence and by the week that the death certificate was filed. Fetal deaths are not included. <sup>†</sup> Pneumonia and influenza.

<sup>1</sup>Because of changes in reporting methods in this Pennsylvania city, these numbers are partial counts for the current week. Complete counts will be available in 4 to 6 weeks. <sup>1</sup>Because of Hurricane Katrina, weekly reporting of deaths has been temporarily disrupted. \*\* Total includes unknown ages.

## FIGURE I. Selected notifiable disease reports, United States, comparison of provisional 4-week totals October 21, 2006, with historical data

Beyond historical limits

\* No measles cases were reported for the current 4-week period yielding a ratio for week 42 of zero (0).
<sup>†</sup> Ratio of current 4-week total to mean of 15 4-week totals (from previous, comparable, and subsequent 4-week periods for the past 5 years). The point where the hatched area begins is based on the mean and two standard deviations of these 4-week totals.

The Morbidity and Mortality Weekly Report (MMWR) Series is prepared by the Centers for Disease Control and Prevention (CDC) and is available free of charge in electronic format. To receive an electronic copy each week, send an e-mail message to *listserv@listserv.cdc.gov*. The body content should read *SUBscribe mmwrtoc*. Electronic copy also is available from CDC's Internet server at *http://www.cdc.gov/mmwr* or from CDC's file transfer protocol server at *ftp://ftp.cdc.gov/pub/publications/mmwr*. Paper copy subscriptions are available through the Superintendent of Documents, U.S. Government Printing Office, Washington, DC 20402; telephone 202-512-1800.

Data in the weekly *MMWR* are provisional, based on weekly reports to CDC by state health departments. The reporting week concludes at close of business on Friday; compiled data on a national basis are officially released to the public on the following Friday. Data are compiled in the National Center for Public Health Informatics, Division of Integrated Surveillance Systems and Services. Address all inquiries about the *MMWR* Series, including material to be considered for publication, to Editor, *MMWR* Series, Mailstop E-90, CDC, 1600 Clifton Rd., N.E., Atlanta, GA 30333 or to *www.mmurq@cdc.gov*.

All material in the MMWR Series is in the public domain and may be used and reprinted without permission; citation as to source, however, is appreciated.

Use of trade names and commercial sources is for identification only and does not imply endorsement by the U.S. Department of Health and Human Services.

References to non-CDC sites on the Internet are provided as a service to *MMWR* readers and do not constitute or imply endorsement of these organizations or their programs by CDC or the U.S. Department of Health and Human Services. CDC is not responsible for the content of these sites. URL addresses listed in *MMWR* were current as of the date of publication.
