## National Disability Awareness Month — October 2007

October is National Disability Awareness Month in the United States. To mark this event, CDC is highlighting activities and interventions that have improved the health of persons with disabilities and reduced health-care costs $(1,2)$. One such intervention is health promotion, which can increase community awareness of the needs of persons with disabilities (3,4).
CDC provides funding to 16 states for healthpromotion programs for persons with disabilities. These 16 states use multiple strategies, including 1) creating a state disability advisory board to assist with strategic planning, development, and implementation of policies that address barriers to accessing health-promotion programs and primary preventive-care services; 2 ) implementing interventions to promote healthy behaviors among persons with disabilities; and 3) partnering with community-based disability organizations (e.g., independent living centers). Additional information regarding state disability and health programs is available at http://www. cdc.gov/ncbddd/dh/dhstateprograms.htm.

## Physical Activity Among Adults With a Disability — United States, 2005

The health benefits of physical activity have been well documented $(1,2)$ and are supported by recommendations from Healthy People 2010 (focus area 22) (3); however, fewer than half of U.S. adults follow these recommendations (4). Physical inactivity is particularly prevalent among adults with a disability (5), who are at increased risk for functional limitations and secondary health conditions (e.g., obesity, depression, or social isolation) (6) that can result from their disabilities, behavior, lifestyle, or environment (1). To estimate the statespecific prevalence of physical activity and physical inactivity among adults with and without a disability, CDC analyzed data from the 2005 Behavioral Risk Factor Surveillance System (BRFSS). This report summarizes the results of that analysis, which determined that, compared with adults without a disability, a smaller proportion of adults with a disability met national recommendations for physical activity ( $37.7 \%$ versus $49.4 \%$ ), and a greater proportion were physically inactive ( $25.6 \%$ versus $12.8 \%$ ). Public health measures to promote and increase physical activity should include consideration for the needs of adults with disabilities.
BRFSS is a state-based, random-digit-dialed telephone survey of the noninstitutionalized, U.S. civilian population aged $\geq 18$ years. In 2005, approximately 350,000 persons from all 50 states, the District of Columbia, Puerto Rico (PR), and the U.S. Virgin Islands (USVI) participated in BRFSS. Consistent with the definition of disability from Healthy People 2010 (3), respondents were asked, "Are you limited in any

way in any activities because of physical, mental, or emotional problems?" and "Do you now have any health problem that requires you to use special equipment, such as a cane, a wheelchair, a special bed, or a special telephone?" Persons who responded yes to either question were classified as having a disability. To measure physical activity, respondents were asked how often they engaged in physical activities of moderate intensity (i.e., brisk walking, bicycling, vacuuming, gardening, or anything else that causes small increases in breathing or heart rate) and vigorous intensity (i.e., running, aerobics, heavy yard work, or anything else that causes large increases in breathing or heart rate) for at least 10 minutes at a time during a usual week.* Respondents were classified as meeting physical activity recommendations if they reported engaging in moderate-intensity activity for $\geq 30$ minutes per day, $\geq 5$ days per week, or vigorous-intensity activity for $\geq 20$ minutes per day, $\geq 3$ days per week. Respondents were classified as physically inactive if they reported participating in moderateintensity or vigorous-intensity activities for $<10$ minutes at a time during a usual week or reported no physical activity during a usual week. The Council of American Survey Research Organizations (CASRO) median response rate for the 2005 BRFSS was 51.1\%

Prevalence estimates were age-adjusted to the 2000 U.S. standard population. Bivariate analyses and chi-square tests were used to compare physical activity levels among those with and those without a disability, and all differences reported were considered to be statistically significant at $\mathrm{p}<0.05$. State-level prevalence estimates and $95 \%$ confidence intervals were calculated.

Nationwide in 2005, an estimated $19.6 \%$ of adults had a disability. Among states and territories, the prevalence of disability ranged from $11.5 \%$ in USVI to $27.1 \%$ in West Virginia (Table). Nationwide, a smaller proportion of adults with a disability engaged in recommended levels of physical activity than respondents without a disability ( $37.7 \%$ versus $49.4 \%$; $\mathrm{p}<0.01$ ). A smaller proportion of adults with a disability met recommended levels for physical activity than adults without a disability in all states and territories except USVI, where the difference was not significant. Among states and territories, the prevalence of persons with a disability who met recommended physical activity levels ranged from $23.2 \%$ in Kentucky to 53.3\% in Alaska.

Nationwide, $25.6 \%$ of persons with a disability reported being physically inactive during a usual week compared with $12.8 \%$ of those without a disability ( $\mathrm{p}<0.01$ ). Adults with a disability were more likely than those without a disability to

[^1]be physically inactive in all states and territories except USVI, where the difference was not significant. Among persons with a disability, the prevalence of physical inactivity ranged from 15.3\% in Utah to $50.2 \%$ in PR.

Reported by: JH Rimmer, PhD, Dept of Disability and Human Development, Univ of Illinois at Chicago. LA Wolf, MPH, BS Armour, PhD, LB Sinclair, MPH, Div of Human Development and Disability, National Center for Birth Defects and Developmental Disabilities, CDC.
Editorial Note: The findings in this report indicate that, in 2005, the proportion of persons without a disability in 28 of 53 ( $52.8 \%$ ) U.S. states and territories surpassed the $50 \%$ target for meeting moderate or vigorous physical activity recommendations set by Healthy People 2010 (objective 22-2). ${ }^{\dagger}$ However, the proportion of persons with a disability surpassed the same target in only two of 53 (3.7\%) states and territories (Table). Furthermore, the findings indicate that the proportion of adults with a disability who were physically inactive ( $25.6 \%$ ) during a usual week was nearly twice the proportion of adults without a disability who were inactive ( $12.8 \%$ ). These results are consistent with those of previous reports finding significant differences in physical activity levels between persons with and without a disability (5).

Physical inactivity among persons with a disability might be more common than among persons without a disability because the inactivity is a consequence of 1 ) the disabling condition itself, 2) physiologic decline (e.g., decreased aerobic capacity, muscular strength and endurance, or flexibility), or 3) lack of access to physical-activity programs and facilities because of personal or environmental barriers ( 7 ). Persons with a disability often experience barriers to regular physical activity that differ from those experienced by the general population, including lack of transportation to fitness centers, lack of information on available and accessible facilities and programs, lack of accessible exercise equipment and adequate space to move about, and the perception that fitness facilities are unfriendly environments for those with a disability (7). Such barriers can result in a decline in physical function and a cycle of deconditioning, in which deteriorating physical function produces greater inactivity, further physical decline, and an increase in the number or severity of secondary conditions (8). To overcome deconditioning, public health officials and others designing strategies to increase adult physical activity should devise ways to eliminate barriers that limit participation by persons with a disability (2).

[^2]The findings in this report are subject to at least two limitations. First, BRFSS excludes persons living in institutions or group homes. Therefore, the results likely underestimate the actual prevalence of adults with a disability. Second, BRFSS questions relating to physical activity were developed and validated for the population without a disability, and the activities described (e.g., brisk walking, bicycling, vacuuming, or running) might be more demanding and difficult for a person with a disability. The need for a physical-activity scale specific to persons with a disability has been suggested (9).
Physical inactivity among persons with a disability is associated with increased functional limitation and higher risk for developing secondary conditions (1,2). Although not all adults with a disability are able to achieve recommended levels of physical activity because of the nature or severity of their disability, participation at lower levels has been determined to confer health benefits (e.g., pain reduction) (2). Persons unable to meet recommended levels might require physicalactivity regimens tailored to their specific needs. In addition, certain barriers to physical activity are unique to persons with a disability. Public health agencies and stakeholders should ensure that barriers to participation are addressed in the design of programs to promote health and physical activity.

## Salmonella Oranienburg Infections Associated with Fruit Salad Served in Health-Care Facilities Northeastern United States and Canada, 2006

During June-July 2006, a total of 41 culture-confirmed Salmonella serotype Oranienburg infections were diagnosed in persons in 10 northeastern U.S. states and one Canadian province. This report describes the epidemiologic, environmental, and laboratory investigations of this outbreak by federal, state, and local health agencies; the Food and Drug Administration (FDA); and the Canadian Food Inspection Agency. The results of the investigations determined that illness was associated with eating fruit salad in health-care facilities. Although the fruit salads were produced by one processing plant, the source of contamination was not determined. This outbreak highlights the importance of laboratory-based surveillance of Salmonella, including molecular subtyping, and timely communication of public health information.

On July 19, 2006, the New Hampshire Department of Health and Human Services (NHDHHS) began an investigation after $S$. Oranienburg was identified in stool specimens collected from two patients, two employees, and one cafeteria patron at a local hospital. On July 21, the Massachusetts Department of Public Health began an investigation after the state public health laboratory identified $S$. Oranienburg in stool specimens collected from three ill persons at a long-termcare facility. State public health laboratories in Massachusetts and New Hampshire subtyped S. Oranienburg isolates by pulsed-field gel electrophoresis (PFGE) and submitted the PFGE patterns to PulseNet, the national molecular subtyping network for foodborne disease surveillance. PulseNet compares these patterns within and among states and categorizes isolates with indistinguishable patterns into potential clusters of cases. The $S$. Oranienburg isolates from New Hampshire and Massachusetts had indistinguishable PFGE patterns (both with $X b a \mathrm{I}$ pattern JJXX01.0056 and $B \ln \mathrm{I}$ pattern JJXA26.0017); this uncommon pattern combination was designated the outbreak strain. NHDHHS coordinated the outbreak investigation with other state health departments, all of which were members of OutbreakNet, a network of local, state, and federal epidemiologists and public health agencies that investigate outbreaks of foodborne, waterborne, and other enteric illnesses.

Epidemiologists were contacted in jurisdictions that reported S. Oranienburg isolates with the outbreak strain during JuneDecember 2006. To develop hypotheses regarding sources of the $S$. Oranienburg infections, NHDHHS reviewed interview
records for all patients who had been interviewed by state and local health departments. Investigators also conducted extended interviews; interviewers sought information regarding nearly 300 sources of exposure, including consumption of 234 specific food items.
A case was defined as culture-confirmed $S$. Oranienburg infection with the outbreak strain and illness onset from June 15 to July 31. Forty-one cases of $S$. Oranienburg with the outbreak strain occurred in 10 U.S. states and one Canadian province: Massachusetts (12), New Hampshire (nine), New York (four), Pennsylvania (three), Vermont (three), Kentucky (two), Maine (two), Maryland (two), Connecticut (one), New Jersey (one), and Ontario, Canada (two). Date of illness onset ranged from June 15 to July 25 (Figure). The median age of patients was 59 years (range: 8 months- 96 years); $31 \%$ of cases were in persons aged $>70$ years. Twenty-eight (68\%) patients were female. Symptoms reported by patients included diarrhea ( $74 \%$ ) (i.e., three or more loose stools in a 24 -hour period), abdominal cramps ( $52 \%$ ), fever ( $39 \%$ ), vomiting ( $23 \%$ ), and bloody diarrhea ( $16 \%$ ). Seven ( $17 \%$ ) patients were hospitalized as a result of their Salmonella infections. No deaths were reported.
Among the 41 cases, 30 ( $73 \%$ ) occurred among persons who worked, stayed, or ate in a health-care facility during the 7 days preceding illness onset, including 10 already-hospitalized patients, 10 residents of a long-term-care facility, nine employees of health-care facilities, and one visitor who had eaten in a hospital cafeteria. The interviews with 33 of the 41 patients suggested that illness was associated with eating fruit salad in a health-care facility; $23(70 \%)$ reported eating fresh fruit salad, $19(83 \%)$ of whom had eaten fresh fruit salad in a health-care facility.

FIGURE. Number of culture-confirmed cases $(\mathrm{N}=41)$ of infection with outbreak strain of Salmonella serotype Oranienburg, by date of illness onset* - United States and Canada, June-July 2006

[^3]A case-control study was conducted to identify risk factors for infection. Case-patients were eligible for the study if they experienced diarrhea, were able to respond to the questionnaire, and had an isolate with the outbreak PFGE patterns. For case-patients who were residents or patients of a healthcare facility, controls were selected randomly from a list of residents or patients who were in the facility at the same time as the case-patient. For case-patients who were employees, controls were selected randomly from a list of employees who worked in the facility at the same time as the case-patient. Controls for community case-patients (i.e., patients who were not exposed as employees or patients in health-care facilities) were well neighbors of the case-patient and were identified through a reverse telephone directory. Controls must not have had diarrhea since June 1 and must have been eating a solid diet during the 7 days before illness onset in the casepatient (i.e., the food-recall period). Based on hypotheses generated during interviews with case-patients, the questionnaire included 75 exposures focused on individual types of fresh fruit and on fruit salad eaten during the foodrecall period. Questionnaires were administered by telephone or in person during August 15-September 6, 2006.
At the time the case-control study was conducted, 36 cases of $S$. Oranienburg had been identified in eight states and Canada. Twenty-two case-patients were eligible for the study; one case-patient chose not to participate and was not enrolled. A total of 21 case-patients and 33 controls were enrolled from all eight states and Canada. Case-control data were analyzed using a fre-quency-matched univariate analysis; three strata were analyzed, with each stratum containing all case-patients and controls for the given exposure location (health-care patients, health-care employees, and community residents). Fourteen ( $70 \%$ ) of 20 case-patients, compared with four ( $13 \%$ ) of 30 controls, ate fruit salad (matched odds ratio $[\mathrm{mOR}]=8.9$; $95 \%$ confidence interval $[C I]=2.3-35.5)$. Illness was associated with eating fruit salad in a health-care facility (Table). Twelve (60\%) of 20 case-patients, compared with four ( $13 \%$ ) of 30 controls, ate fruit salad in a health-care facility ( $\mathrm{mOR}=6.0 ; \mathrm{CI}=1.5-23.5$ ). Salads eaten by case-patients were composed of multiple types of fruits; cantaloupe and honeydew melon were the most common fruits in salads eaten in health-care facilities. Cantaloupe was eaten by $10(50 \%)$ case-patients and two ( $7 \%$ ) controls $(\mathrm{mOR}=7.6 ; \mathrm{CI}=1.6-$
36.7); honeydew melon was eaten by nine ( $45 \%$ ) case-patients and one ( $3 \%$ ) control ( $\mathrm{mOR}=14.2$; $\mathrm{CI}=1.8-112.5$ ). Illness was not associated with consumption of individual fruits that were not part of a fruit salad. Use of multivariate analysis with conditional logistic regression was not feasible because of high consumption of multiple types of fruit.

Of 13 health-care facilities with case-patients, information regarding the source of the fruit served was collected for 11 facilities, 10 ( $91 \%$ ) of which had served refrigerated, precut cantaloupe and honeydew melon purchased from the same processing plant in Canada. Inspections of the processing plant by the Canadian Food Inspection Agency did not identify any improper practices and determined that the plant was in compliance with its Hazard Analysis and Critical Control Points (HACCP) plan. The processing plant had received the fruit from multiple farms. At the plant, fruit was cleaned, sliced, packaged into containers, and refrigerated. Health-care facilities received the refrigerated, precut fruit as either a premixed fruit salad or as individual fruits that later were mixed on-site by the health-care facility. A traceback investigation of the original source of the cantaloupe and honeydew melons processed in the facility during June 1-July 15 indicated that the cantaloupe and honeydew melons likely originated from the

[^4]United States; however, no specific farm was identified. No salmonellae were isolated from fruit salad samples collected at health-care facilities with outbreak-related cases or from samples collected by FDA at the point of entry into the United States. The Canadian Food Inspection Agency did not collect samples from the processing plant.

M Lynch, MD, CK Olson, MD, Div of Foodborne, Bacterial, and Mycotic Diseases, National Center for Zoonotic, Vector-Borne, and Enteric Diseases, CDC.
Editorial Note: Salmonellae infect an estimated 1.2 million persons each year in the United States (1). In 2005, 1 year before the outbreak described in this report, a total of 36,184 Salmonella infections reported in the United States were laboratory confirmed; 590 (1.6\%) were $S$. Oranienburg (2). The 41 cases in this international outbreak highlight the importance of laboratory-based surveillance, which relies on routine submission of Salmonella isolates from clinical laboratories to state public health laboratories. Furthermore, this outbreak illustrates the importance of sharing public health information domestically and internationally, because the investigation relied on the timely sharing of information among 10 state health departments, two national health agencies, two national food-regulatory agencies, and multiple local and provincial health departments.
The findings of this investigation indicated that infection with an uncommon strain of $S$. Oranienburg was associated with consumption of fruit salad in health-care facilities. The findings indicated that 1) $70 \%$ of case-patients ate fruit salad,
2) case-patients were six times more likely than controls to have eaten fruit salad in a health-care facility, and 3) 10 ( $91 \%$ ) of 11 health-care facilities with Salmonella infections served refrigerated, precut fruit salad from the same processing plant in Canada. The source of the contamination of the fruit salad was not determined. However, because the fruit salad at the various health-care facilities was provided by several distributors but came from a common processing plant, contamination likely occurred either at the processing plant or earlier in the supply chain, such as at a farm.

Fruits such as cantaloupe and honeydew melon previously have been associated with salmonellosis outbreaks in the United States. During 1973-2003, a total of 11 cantaloupeassociated salmonellosis outbreaks were reported to CDC (3).

Reported outbreaks were associated both with whole melons contaminated in growing fields and with precut melons. Cut fruit can be contaminated during processing when rind is removed and fruit is sliced $(4,5)$. Furthermore, because the inner flesh of melons contains nutrients that can support microbial growth, improper refrigeration of cut fruit can cause bacteria proliferation (4,5). Although $S$. Oranienburg was not identified in any of the fruit salad samples collected, the samples were obtained several weeks after illness-onset dates in case-patients.

Salmonella outbreaks have not been frequently identified in health-care facilities in the United States, perhaps because not all cases are recognized. Current guidelines for the management of diarrhea discourage testing for Salmonella in hospitalized patients who have been in a facility for $>72$ hours unless an outbreak is suspected, the diarrhea is bloody, or the patient is an infant ( $)$. These guidelines might make health-care facilities less likely to detect outbreaks of salmonellosis or recognize that they are part of larger outbreaks, such as the one discussed in this report $(7,8)$. During this outbreak, only two of the 13 health-care facilities with cases recognized that an outbreak was occurring, likely because most facilities only identified one or two cases. In the Massachusetts and New Hampshire facilities, the initial outbreaks were recognized after three and five cases were identified in each facility, respectively. After both facilities implemented an active surveillance program for staff members and patients, eight additional cases were identified, suggesting that certain cases might not have been detected in the facilities that adhered to the 72 -hour testing policy. Evaluation is needed to determine whether expanding the criteria for bacterial testing of stool specimens from inpatients beyond the presence of bloody diarrhea would improve foodborne outbreak detection and ultimately the safety of the food supply.

## Progress in Measles Control Nepal, 2000-2006

In 2002, the United Nations General Assembly Special Session on Children set a goal to reduce global measles deaths by half (compared with 1999) by 2005 (1). Nepal, a southeast Asian country with an estimated population of 27 million, adopted the measles mortality reduction strategies of the World Health Organization (WHO) (2) in 2003, with a goal of reducing measles deaths by half (compared with 2003) by 2005. The strategies consisted of strengthening routine childhood immunization programs, providing a second opportunity for measles vaccination through supplementary immunization activities (SIAs),* improving surveillance, and improving measles case management. This report describes routine immunization activities in Nepal, the implementation of measles SIAs, and measles surveillance data for the period 2000-2006. The findings demonstrate a substantial decrease in reported measles incidence. Assuming a reduction in measles deaths that paralleled the decrease in incidence, the findings also suggest progress toward the goal of measles mortality reduction.

[^5]
## Background and Routine Vaccination

Nepal is divided into 75 districts in five regions. The Expanded Programme on Immunization (EPI) was initiated in 1979 in Nepal in three districts; by 1988, the program had been expanded to all 75 districts (3). The program aims to achieve and maintain coverage of $\geq 90 \%$ fully immunized ${ }^{\dagger}$ children nationwide by 2010 (4) and targets children aged $\geq 9$ months with measles vaccine. According to WHO/ UNICEF estimates, measles vaccination coverage among children aged <1 year increased from $58 \%$ in 1988 to $71 \%$ in 2000; coverage further increased from $75 \%$ in 2003 to $85 \%$ in 2006 (5). Despite high national coverage in 2006, six of 75 districts (representing $4 \%$ of the population aged $<5$ years) were unable to reach $>70 \%$ coverage because of lack of security resulting from civil unrest, limited access to certain areas, or lack of human resources.

## Surveillance

Measles in Nepal is reported as part of the Health Management Information System (HMIS), which covers all 4,102 government health facilities in Nepal. However, HMIS does not provide detailed geographic and age group data, and reports often are incomplete and not timely; moreover, HMIS reports only clinically suspected measles and does not report laboratory testing. Information on measles-related deaths is not reported systematically. In March 2003, the government of Nepal and WHO initiated a more comprehensive measles surveillance system to supplement HMIS with more detailed information on cases in clusters of suspected measles. The new measles surveillance system, which includes field investigations and laboratory testing of blood specimens, is supported by surveillance medical officers (SMOs), who have conducted health facility visits for active acute flaccid paralysis (AFP) surveillance since 1998. This integrated surveillance network provides timely and detailed data on AFP, Japanese encephalitis, and measles cases though weekly reports from 413 major health-care centers and hospitals throughout all 75 districts of the country (i.e., approximately $10 \%$ of all government health facilities), including all inpatient facilities. In addition, SMOs conduct weekly visits to 84 active surveillance sites within this network.
If five or more cases of suspected measles are detected during a 2 -week period from one geographic area, an outbreak investigation is undertaken in which epidemiologic informa-

[^6]tion is collected on all suspected measles cases ${ }^{\$}$ in the area, and blood samples are drawn for at least five cases for laboratory confirmation of measles (i.e., via identification of immunoglobulin $\mathrm{M}[\mathrm{IgM}]$ measles antibodies). An outbreak is considered a confirmed measles outbreak if at least one case is laboratory confirmed in a person who had not received measles vaccination 1 month before. All untested suspected cases in a laboratory-confirmed outbreak are considered epidemiologically confirmed. Since January 2004, all samples that test negative for measles $\operatorname{IgM}$ have been tested for rubella IgM . With rubella IgM testing, similar criteria allow an outbreak to be considered a confirmed rubella outbreak or a confirmed mixed measles and rubella outbreak. Approximately $90 \%$ of cases associated with confirmed measles outbreaks in 2003 were in children aged $<15$ years; this finding supported the decision to conduct a "catch-up" SIA ${ }^{9}$ targeting children aged 9 months- 15 years.

## Measles Vaccination Campaign, 2004-2005

Nepal public health authorities conducted a nationwide measles SIA in three phases during September 2004-April 2005, targeting an estimated 9.4 million children aged 9 months15 years. Oral poliovirus vaccine also was administered to all children aged <5 years. The overall reported measles vaccina-

[^7]tion coverage was $105 \%$ of the population target; in one district the coverage was as low as $64 \%$. The population targets were obtained from administrative lists.

## Measles Incidence

In 2003, a total of 67 suspected measles outbreaks were investigated using the integrated system; in 2004, a total of 196 outbreaks were investigated. Nearly $70 \%$ of these outbreaks were confirmed measles outbreaks (Table). After the start of the SIAs, the number of suspected measles outbreaks detected decreased to 46 in 2005 and to 31 in 2006. In 2005, only one ( $2 \%$ ) of the 46 investigated outbreaks was a laboratory-confirmed measles outbreak, whereas 36 (78\%) were laboratory-confirmed rubella outbreaks. Similarly, in 2006, two ( $6 \%$ ) of 31 outbreaks were laboratory-confirmed measles outbreaks, and 24 ( $77 \%$ ) were laboratory-confirmed rubella outbreaks. During 2005 and 2006, three mixed measles and rubella outbreaks were detected: two ( $4 \%$ ) in 2005 and one ( $3 \%$ ) in 2006. The number of measles cases associated with outbreaks decreased from approximately 1,000 in 2003 to approximately 50 in 2006. During 2005 and 2006, a total of 1,119 suspected measles cases that were not part of any recognized outbreak were reported to SMOs. Serum specimens were collected for 84 of these cases; three ( $4 \%$ ) were laboratory confirmed as measles cases.
The average annual number of measles cases reported through HMIS during the 4 years (2000-2003) before the start of the SIA was 10,425 . After the SIA, the number of reported cases decreased to 3,931 in 2005 and to 1,935 in 2006 , decreases of $62 \%$ and $81 \%$, respectively, from the 20002003 average (Table, Figure).

O Mach, MD, VDietz, MD, Global Immunization Div, National Center for Immunization and Respiratory Diseases, CDC.
Editorial Note: Because information on measles-related deaths is not routinely collected in Nepal, no direct measurement of reduction in deaths associated with improved measles control is possible. However, reports from other countries have assumed that a reduction in measles deaths occurred in the same proportion as a reduction in reported measles cases $(6,7)$. A concomitant decrease in suspected cases and measles deaths has been observed in other countries that monitored measles deaths before and after SIAs $(8,9)$. By making this same assumption for Nepal, the findings in this report suggest that, by the end of 2005, Nepal had achieved its goal of reducing measles mortality by at least $50 \%$ from 2003 levels. The reduction in measles incidence in Nepal during 2003-2006 indicated by HMIS data might underestimate the actual relative reduction in measles deaths because, compared with pre-SIA years, a more pronounced decrease occurred in the number of confirmed outbreaks and in the proportion of confirmed measles cases in outbreaks during post-SIA years. In addition, treatment of measles patients** has been emphasized since 2003.

On the basis of progress to date, the government of Nepal has decided to set its measles program objective toward elimination. In the Ministry of Health and Population's Multi-Year Plan of Action for immunization, the measles elimination phase will begin in 2010 (4). Major components of the elimination strategy include high routine immunization coverage ( $\geq 90 \%$ in $\geq 80 \%$ of districts), provision of a second opportunity for measles vaccination through routine vaccination or SIAs, and case-based surveillance with laboratory confirmation.

[^9]FIGURE. Number of measles cases from confirmed measles outbreaks, by month and year - Nepal, 2003-2006*

*Based on data from the Health Management Information System, Department of Health Services, ${ }^{+}$Nepal Ministry of Health and Population.
${ }^{\dagger}$ Supplementary immunization activity.

The integration of measles surveillance and AFP surveillance since 2003 has made use of the extensive surveillance infrastructure in Nepal, which was developed for AFP surveillance and, since 2004, has included investigation and laboratory testing of suspected encephalitis cases for Japanese B encephalitis. WHO formally accredited the Nepal national measles reference laboratory in 2006. The first steps toward further strengthening surveillance began in January 2007; a case-based measles surveillance system, in which all suspected measles cases are investigated and laboratory tested for $\operatorname{IgM}$, was started in 12 active surveillance sites in the Kathmandu Valley and in two active surveillance sites in the Far West Development Region. In addition to continuing outbreak investigations, this case-based surveillance system will expand to include the entire country by 2010 and will use measles virus genotyping to determine the origin of virus isolates; however, data on measles-related mortality are not available through this system.

Additional measures to increase routine vaccination coverage, particularly in remote areas and those with low coverage, will be critical for preventing outbreaks and moving toward the goal of measles elimination. Despite advances in delivering routine vaccination, the proportion of children susceptible to measles started to increase after the 2004-2005 SIA,
increasing the likelihood of measles outbreaks. A nationwide follow-up measles vaccination campaign ${ }^{\dagger \dagger}$ targeting children aged 9 months to 4 years 11 months is planned for 2008. Given the difficulties with access to certain areas of Nepal, providing a second measles vaccination opportunity through routine vaccination is not likely to reach high coverage levels with both doses. Because SIAs have been effective throughout Nepal, including in areas that are difficult to access, repeated SIAs likely will be the long-term strategy for regularly providing a second measles vaccination opportunity.

Nepal has achieved a substantial reduction in reported measles incidence and in the number of confirmed measles outbreaks. This experience provides useful lessons for other countries in southeast Asia as they progress toward measles mortality reduction.

TABLE I. Provisional cases of infrequently reported notifiable diseases (<1,000 cases reported during the preceding year) - United States, week ending September 29, 2007 (39th Week)*

-: No reported cases. N: Not notifiable. Cum: Cumulative year-to-date counts.

* Incidence data for reporting year 2007 are provisional, whereas data for 2002, 2003, 2004, 2005, and 2006 are finalized.
$\dagger$ Calculated by summing the incidence counts for the current week, the 2 weeks preceding the current week, and the 2 weeks following the current week, for a total of 5 preceding years. Additional information is available at http://www.cdc.gov/epo/dphsi/phs/files/5yearweeklyaverage.pdf.
§ Not notifiable in all states. Data from states where the condition is not notifiable are excluded from this table, except in 2007 for the domestic arboviral diseases and influenzaassociated pediatric mortality, and in 2003 for SARS-CoV. Reporting exceptions are available at http://www.cdc.gov/epo/dphsi/phs/infdis.htm.
II Includes both neuroinvasive and nonneuroinvasive. Updated weekly from reports to the Division of Vector-Borne Infectious Diseases, National Center for Zoonotic, VectorBorne, and Enteric Diseases (ArboNET Surveillance). Data for West Nile virus are available in Table II.
** Data for H. influenzae (all ages, all serotypes) are available in Table II.
$\dagger \dagger$ Updated monthly from reports to the Division of HIV/AIDS Prevention, National Center for HIV/AIDS, Viral Hepatitis, STD, and TB Prevention. Implementation of HIV reporting influences the number of cases reported. Updates of pediatric HIV data have been temporarily suspended until upgrading of the national HIV/AIDS surveillance data management system is completed. Data for HIV/AIDS, when available, are displayed in Table IV, which appears quarterly.
$\$ \S$ Updated weekly from reports to the Influenza Division, National Center for Immunization and Respiratory Diseases. A total of 70 cases were reported for the 2006-07 flu season.
ๆाी The two measles cases reported for the current week were indigenous.
*** Data for meningococcal disease (all serogroups) are available in Table II
tit No rubella cases were reported for the current week.
§s§ Updated weekly from reports to the Division of Viral and Rickettsial Diseases, National Center for Zoonotic, Vector-Borne, and Enteric Diseases.

* Incidence data for reporting year 2007 are provisional.
${ }^{\top}$ Updated weekly from reports to the Division of Vector-Borne Infectious Diseases, National Center for Zoonotic, Vector-Borne, and Enteric Diseases (ArboNET Surveillance). Data § for California serogroup, eastern equine, Powassan, St. Louis, and western equine diseases are available in Table I.
${ }^{5}$ Not notifiable in all states. Data from states where the condition is not notifiable are excluded from this table, except in 2007 for the domestic arboviral diseases and influenza-
associated pediatric mortality, and in 2003 for SARS-CoV. Reporting exceptions are available at http://www.cdc.gov/epo/dphsi/phs/infdis.htm.
Contains data reported through the National Electronic Disease Surveillance System (NEDSS).

U: Unavailable. -: No reported cases.
${ }^{*}$ Mortality data in this table are voluntarily reported from 122 cities in the United States, most of which have populations of $\geq 100,000$. A death is reported by the place of its occurrence and by the week that the death certificate was filed. Fetal deaths are not included.
${ }^{\dagger}$ Preumonia and influenza.
${ }^{\text {s }}$ Because of changes in reporting methods in this Pennsylvania city, these numbers are partial counts for the current week. Complete counts will be available in 4 to 6 weeks.
${ }^{\pi}$ "Because of Hurricane Katrina, weekly reporting of deaths has been temporarily disrupted.
** Total includes unknown ages.

FIGURE I. Selected notifiable disease reports, United States, comparison of provisional 4-week totals September 29, 2007, with historical data

* Ratio of current 4-week total to mean of 154 -week totals (from previous, comparable, and subsequent 4-week periods for the past 5 years). The point where the hatched area begins is based on the mean and two standard deviations of these 4-week totals.

[^16]The Morbidity and Mortality Weekly Report (MMWR) Series is prepared by the Centers for Disease Control and Prevention (CDC) and is available free of charge in electronic format. To receive an electronic copy each week, send an e-mail message to listserv@listserv.cdc.gov. The body content should read SUBscribe mmwr$t o c$. Electronic copy also is available from CDC's Internet server at http://www.cdc.gov/mmwr or from CDC's file transfer protocol server at ftp://ftp.cdc.gov/pub/ publications/mmwr. Paper copy subscriptions are available through the Superintendent of Documents, U.S. Government Printing Office, Washington, DC 20402; telephone 202-512-1800.

Data in the weekly $M M W R$ are provisional, based on weekly reports to CDC by state health departments. The reporting week concludes at close of business on Friday; compiled data on a national basis are officially released to the public on the following Friday. Data are compiled in the National Center for Public Health Informatics, Division of Integrated Surveillance Systems and Services. Address all inquiries about the MMWR Series, including material to be considered for publication, to Editor, MMWR Series, Mailstop E-90, CDC, 1600 Clifton Rd., N.E., Atlanta, GA 30333 or to www.mmwrq@cdc.gov.

All material in the $M M W R$ Series is in the public domain and may be used and reprinted without permission; citation as to source, however, is appreciated.
Use of trade names and commercial sources is for identification only and does not imply endorsement by the U.S. Department of Health and Human Services.
References to non-CDC sites on the Internet are provided as a service to $M M W R$ readers and do not constitute or imply endorsement of these organizations or their programs by CDC or the U.S. Department of Health and Human Services. CDC is not responsible for the content of these sites. URL addresses listed in $M M W R$ were current as of the date of publication.

[^1]:    
     having a disability.
    
     heart rate) for $\geq 20$ minutes per day, $\geq 3$ days per week.
    § Reported participating in moderate-intensity or vigorous-intensity activities for $<10$ minutes at a time or reported no physical activity during a usual week.
    T Confidence interval.

[^2]:    ${ }^{\dagger}$ Healthy People 2010 midcourse review: physical activity and fitness. Available at http://www.healthypeople.gov/data/midcourse/pdf/fa22.pdf.

[^3]:    * If illness onset date was unknown, date of specimen collection was used.

[^4]:    *Case-patients and controls were excluded from analysis if the relevant interview question
    †was not answered or the respondent answered "unknown."
    ${ }_{\S}^{\dagger}$ Confidence interval.
    ${ }^{\text {§ }}$ Calculation uses a 0.5 continuity correction because of stratum cells that contain zero.

[^5]:    *Mass campaigns conducted during a short period (days to weeks) in which a dose of measles-containing vaccine is administered to all children in a targeted age group (e.g., 9 months -15 years), regardless of previous vaccination history. Campaigns can be conducted nationally or in portions of the country.

[^6]:    ${ }^{\dagger}$ A fully immunized child is a child who, by his or her first birthday, has received 1 dose of bacille Calmette-Guérin vaccine; 3 doses of diphtheria, tetanus, and pertussis vaccine; 3 doses of oral poliovirus vaccine; and 1 dose of measlescontaining vaccine.

[^7]:    ${ }^{\$}$ For surveillance purposes, a suspected case of measles is defined as generalized maculopapular rash and fever plus one of the following: cough, coryza (i.e., runny nose), or conjunctivitis (i.e., red eyes). Additional information available at http://www.afro.who.int/measles/guidelines/index.html.
    ${ }^{\text {I }}$ Catch-up campaigns are one-time events targeting all children in a particular age group. The goal is to vaccinate all children who might not have been previously vaccinated for the first time against measles and provide a second opportunity for measles vaccination in addition to routine vaccination. During a catch-up campaign, all children in the targeted age group receive a supplementary dose of measles vaccine, regardless of previous disease or vaccination history. Additional information is available at http:// www.measlesinitiative.org/vaccination.asp.

[^8]:    * Based on data from the Health Management Information System, Department of Health Services, Nepal Ministry of Health and Population.
    ${ }_{\S}^{\dagger}$ Based on data from the World Health Organization/Nepal Ministry of Health and Population integrated vaccine-preventable disease surveillance network.
    § Outbreak investigations and laboratory testing started in March 2003.
    ${ }^{9}$ Laboratory confirmation for rubella-specific immunoglobulin M did not start until January 2004.

[^9]:    ** Treatment includes administration of vitamin A and, if complications are noted, antibiotics. Additional information available at http://www.who.int/ mediacentre/factsheets/fs286/en.

[^10]:    $\dagger \dagger$ Follow-up SIAs are conducted periodically (i.e., every $3-5$ years) to maintain low levels of susceptibility. A follow-up campaign provides children with a second opportunity for measles vaccination and aims to reach all children aged $\geq 9$ months who were born after the previous catch-up campaign. Additional information available at http://www.measlesinitiative.org/ vaccination.asp.
